Dynamic Set Operations

- S. search(k): Returns pointer to object x from S with key[x] = k or null.
- S. insert(x): Inserts object x into set S. key[x] must not currently exist in the data-structure.
- S. delete(x): Given pointer to object x from S, delete x from the set.
- S. minimum(): Return pointer to object with smallest key-value in S.
- S. maximum(): Return pointer to object with largest key-value in S.
- S. successor(x): Return pointer to the next larger element in S or null if x is maximum.
- S. predecessor(x): Return pointer to the next smaller element in S or null if x is minimum.

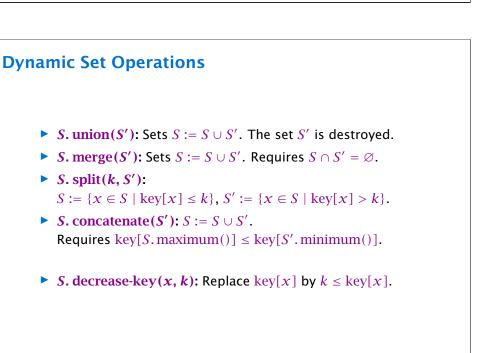

Abstract Data Type

An abstract data type (ADT) is defined by an interface of operations or methods that can be performed and that have a defined behavior.

The data types in this lecture all operate on objects that are represented by a [key, value] pair.

- The key comes from a totally ordered set, and we assume that there is an efficient comparison function.
- The value can be anything; it usually carries satellite information important for the application that uses the ADT.

Harald Räcke

6. Feb. 2022

Examples of ADTs

Stack:

- ► *S*. push(*x*): Insert an element.
- S. pop(): Return the element from S that was inserted most recently; delete it from S.
- **S. empty()**: Tell if *S* contains any object.

Queue:

- S. enqueue(x): Insert an element.
- S. dequeue(): Return the element that is longest in the structure; delete it from S.
- **S. empty()**: Tell if *S* contains any object.

Priority-Queue:

- S. insert(x): Insert an element.
- S. delete-min(): Return the element with lowest key-value; delete it from S.

7 Dictionary

Dictionary:

- S. insert(x): Insert an element x.
- S. delete(x): Delete the element pointed to by x.
- S. search(k): Return a pointer to an element e with key[e] = k in S if it exists; otherwise return null.

Harald Räcke

7 Dictionary

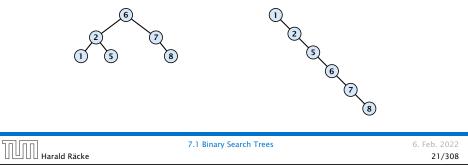

6. Feb. 2022 20/308

7.1 Binary Search Trees

An (internal) binary search tree stores the elements in a binary tree. Each tree-node corresponds to an element. All elements in the left sub-tree of a node v have a smaller key-value than key[v] and elements in the right sub-tree have a larger-key value. We assume that all key-values are different.

(External Search Trees store objects only at leaf-vertices)

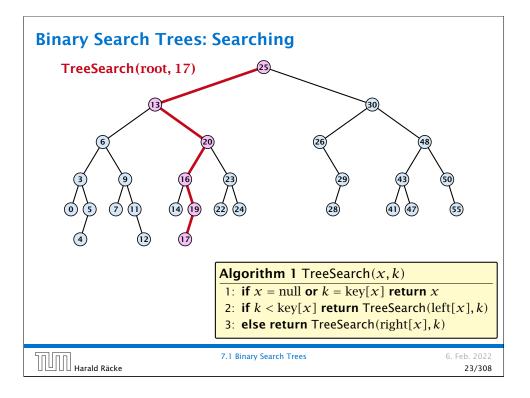

Examples:

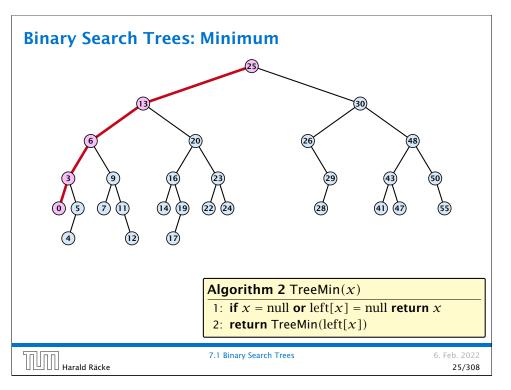

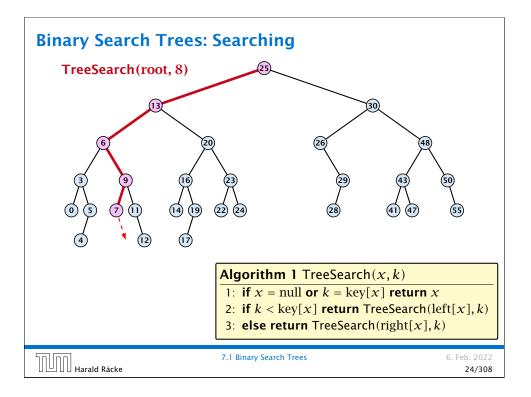

7.1 Binary Search Trees

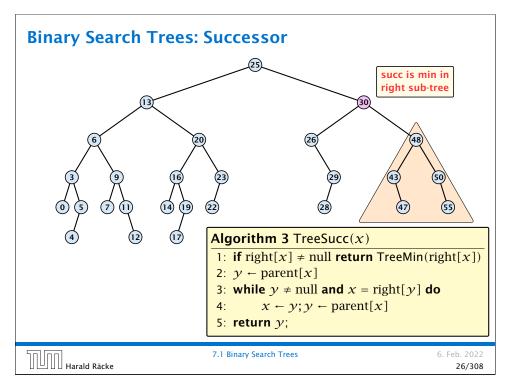

We consider the following operations on binary search trees. Note that this is a super-set of the dictionary-operations.

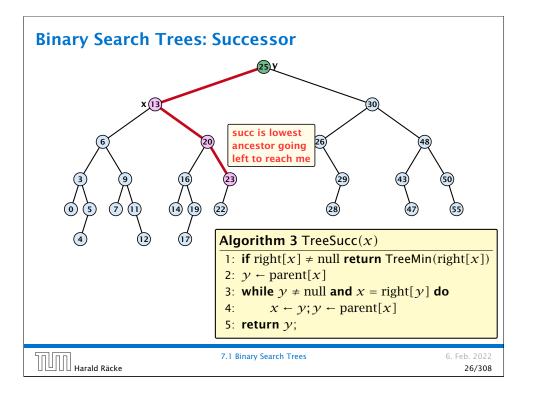

- \blacktriangleright T. insert(x)
- ► *T*. delete(*x*)
- ► T. search(k)
- ► T. successor(x)
- ► T. predecessor(x)
- ► T. minimum()
- ► T. maximum()

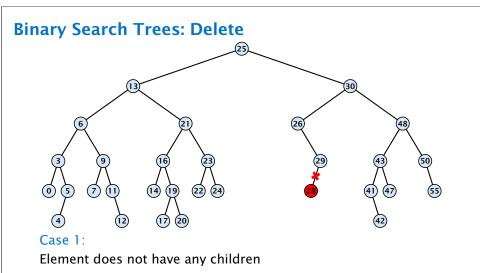

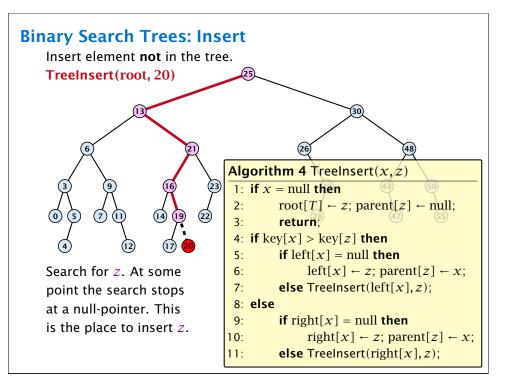

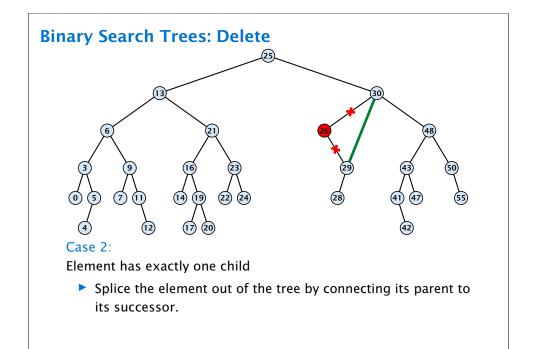

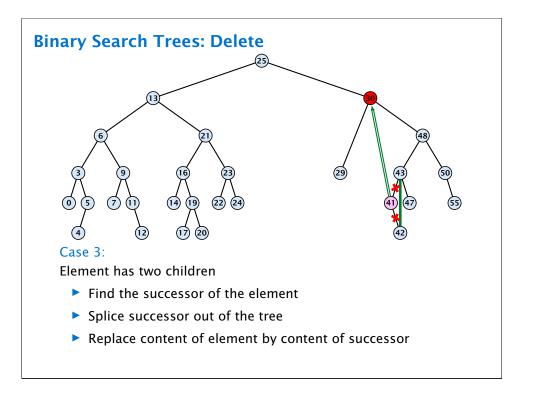

Simply go to the parent and set the corresponding pointer to null.

Binary Search Trees: Delete

	= null or right[z] = null

Balanced Binary Search Trees

All operations on a binary search tree can be performed in time $\mathcal{O}(h)$, where h denotes the height of the tree.

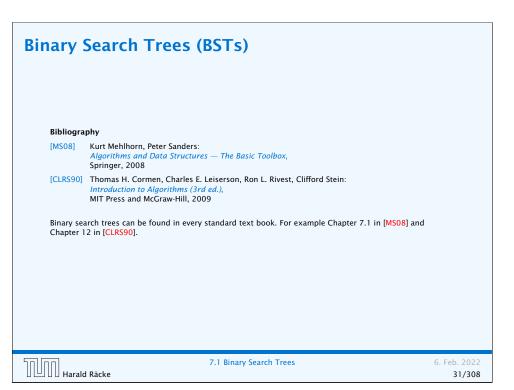

However the height of the tree may become as large as $\Theta(n)$.

Balanced Binary Search Trees

With each insert- and delete-operation perform local adjustments to guarantee a height of $O(\log n)$.

AVL-trees, Red-black trees, Scapegoat trees, 2-3 trees, B-trees, AA trees, Treaps

similar: SPLAY trees.

7.2 Red Black Trees

Definition 1

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- **3.** For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data

	7.2 Red

d Black Trees

7.2 Red Black Trees

Lemma 2

A red-black tree with n internal nodes has height at most $O(\log n)$.

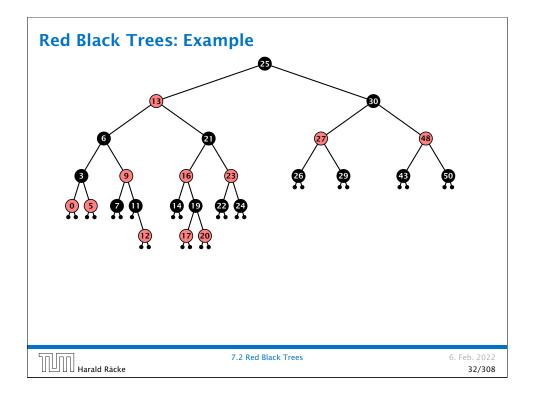

Definition 3

The black height bh(v) of a node v in a red black tree is the number of black nodes on a path from v to a leaf vertex (not counting v).

We first show:

Lemma 4

A sub-tree of black height $bh(\upsilon)$ in a red black tree contains at least $2^{bh(\upsilon)}-1$ internal vertices.

7.2 Red Black Trees	
Proof of Lemma 4.	
Induction on the height of v .	
base case (h eight(v) = 0)	
 If height(v) (maximum distance btw. v and a node in the sub-tree rooted at v) is 0 then v is a leaf. The black height of v is 0. The sub-tree rooted at v contains 0 = 2^{bh(v)} - 1 inner vertices.

7.2 Red Black Trees

7.2 Red Black Trees

Definition 1

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- **3.** For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data.

Harald Räcke

6. Feb. 2022 37/308

7.2 Red Black Trees

Proof of Lemma 2.

Let h denote the height of the red-black tree, and let P denote a path from the root to the furthest leaf.

At least half of the node on P must be black, since a red node must be followed by a black node.

Hence, the black height of the root is at least h/2.

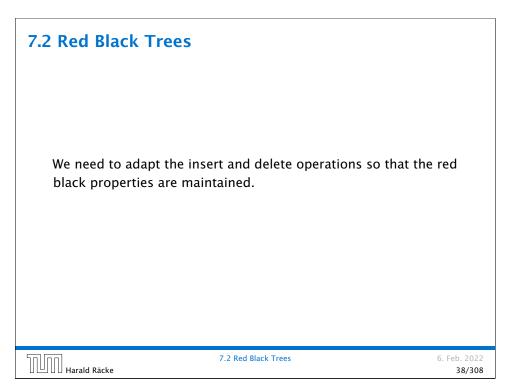

The tree contains at least $2^{h/2} - 1$ internal vertices. Hence, $2^{h/2} - 1 \le n$.

Hence, $h \leq 2\log(n+1) = O(\log n)$.

Harald Räcke

7.2 Red Black Trees

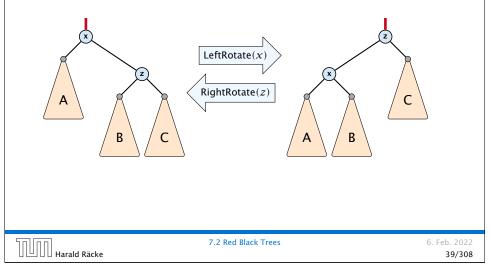

6. Feb. 2022 36/308

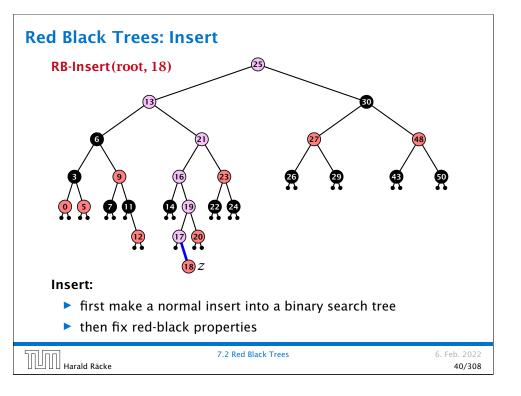

Rotations

|||||||| Harald Räcke

The properties will be maintained through rotations:

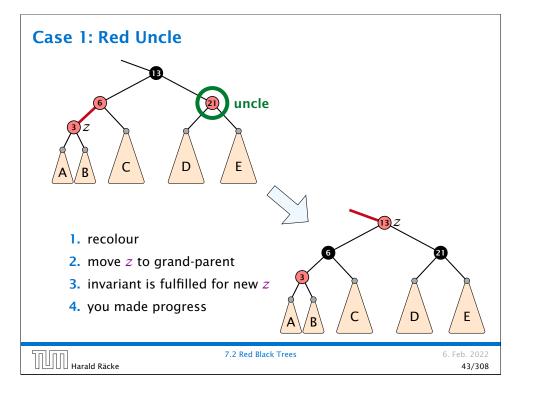

Red Black Trees: Insert Invariant of the fix-up algorithm: > z is a red node > the black-height property is fulfilled at every node > the only violation of red-black properties occurs at z and parent[z] > either both of them are red (most important case) > or the parent does not exist (violation since root must be black) If z has a parent but no grand-parent we could simply color the parent/root black; however this case never happens.

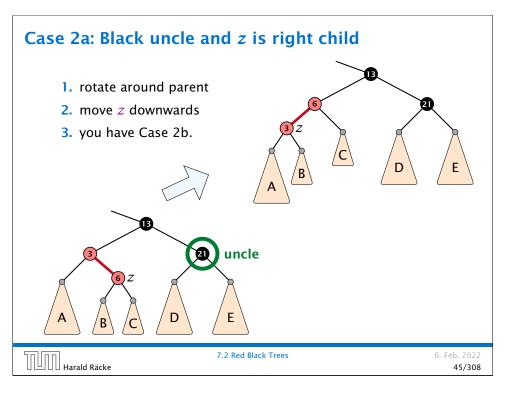

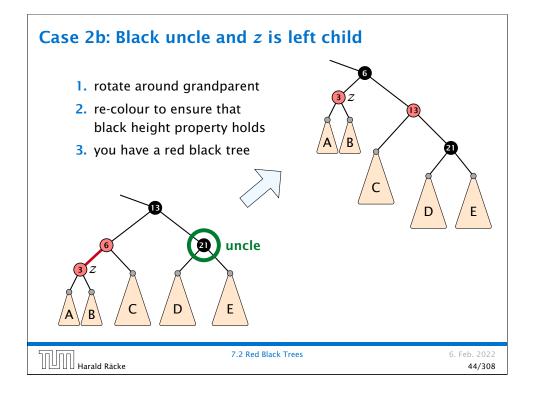

Algo	rithm 10 InsertFix (z)	
1: N	hile parent[z] \neq null and col[parent[z]]	= red do
2:	if parent[z] = left[gp[z]] then z in left	subtree of grandparent
3:	$uncle \leftarrow right[grandparent[z]]$	
4:	<pre>if col[uncle] = red then</pre>	Case 1: uncle red
5:	$\operatorname{col}[p[z]] \leftarrow \operatorname{black}; \operatorname{col}[u] \leftarrow \operatorname{black};$	ack;
6:	$\operatorname{col}[\operatorname{gp}[z]] \leftarrow \operatorname{red}; z \leftarrow \operatorname{grandpa}$	rent[z];
7:	else	Case 2: uncle black
8:	if $z = right[parent[z]]$ then	2a: z right child
9:	$z \leftarrow p[z]; LeftRotate(z);$	
10:	$\operatorname{col}[p[z]] \leftarrow \operatorname{black}; \operatorname{col}[gp[z]] \cdot$	- red; 2b: <i>z</i> left child
11:	RightRotate $(gp[z]);$	
12:	else same as then-clause but right and	left exchanged
13: C	$ol(root[T]) \leftarrow black;$	

Harald Räcke

6. Feb. 2022 41/308

Red Black Trees: Insert Running time:

- Only Case 1 may repeat; but only h/2 many steps, where h is the height of the tree.
- $\blacktriangleright Case 2a \rightarrow Case 2b \rightarrow red-black tree$
- Case $2b \rightarrow red$ -black tree

Performing Case 1 at most $O(\log n)$ times and every other case at most once, we get a red-black tree. Hence $O(\log n)$ re-colorings and at most 2 rotations.

Red Black Trees: Delete

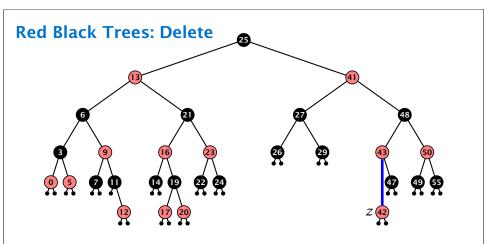

First do a standard delete.

If the spliced out node x was red everything is fine.

If it was black there may be the following problems.

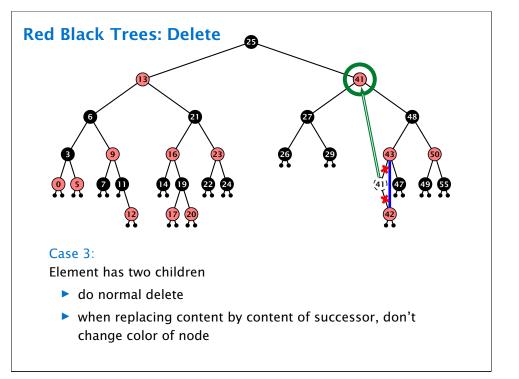

- Parent and child of x were red; two adjacent red vertices.
- If you delete the root, the root may now be red.
- Every path from an ancestor of x to a descendant leaf of x changes the number of black nodes. Black height property might be violated.

Harald Räcke	7.2 Red Black Trees	6. Feb. 2022 47/308

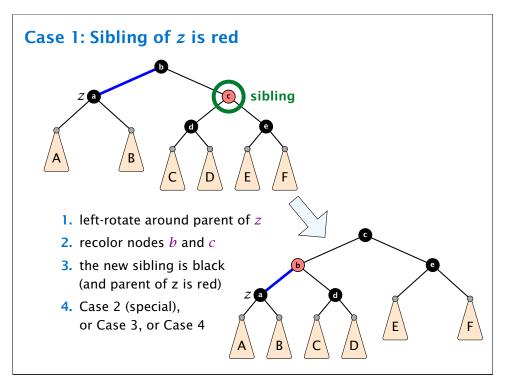

Delete:

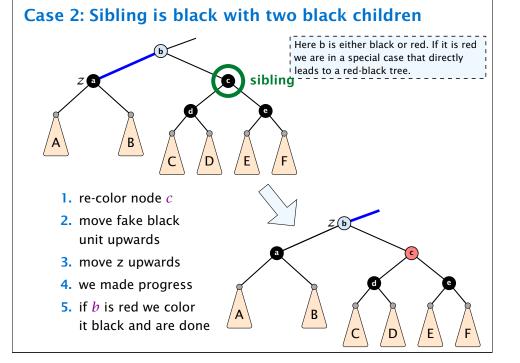

- deleting black node messes up black-height property
- if z is red, we can simply color it black and everything is fine
- the problem is if z is black (e.g. a dummy-leaf); we call a fix-up procedure to fix the problem.

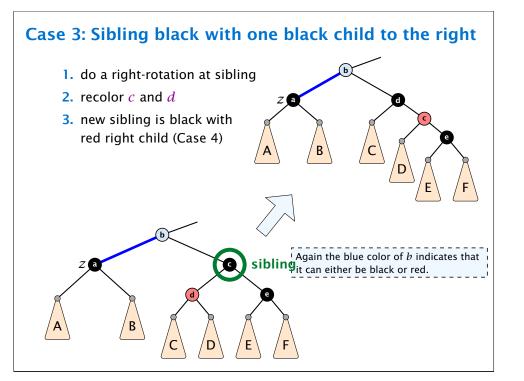

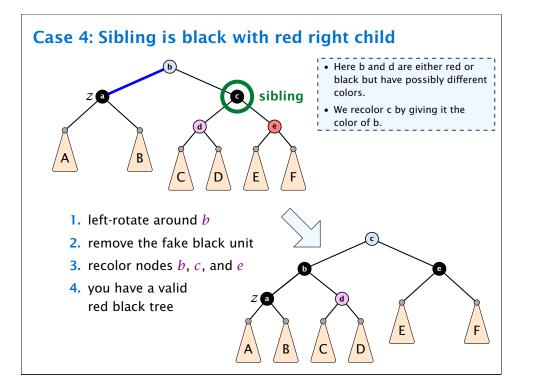

ed Black Trees	: Delete	
Invariant of the f	ix-up algorithm	
the node z is	black	
	' a fake black unit to the edge he black-height property is ful	
	ons in such a way that you at s plack unit from the edge.	some point can

7.2 Red Black Trees

Running time:

- only Case 2 can repeat; but only h many steps, where h is the height of the tree
- Case 1 → Case 2 (special) → red black tree Case 1 → Case 3 → Case 4 → red black tree Case 1 → Case 4 → red black tree
- Case 3 \rightarrow Case 4 \rightarrow red black tree
- Case $4 \rightarrow$ red black tree

Performing Case 2 at most $O(\log n)$ times and every other step at most once, we get a red black tree. Hence, $O(\log n)$ re-colorings and at most 3 rotations.

Harald Räcke	7.

7.2 Red Black Trees

6. Feb. 2022 55/308

Splay Trees

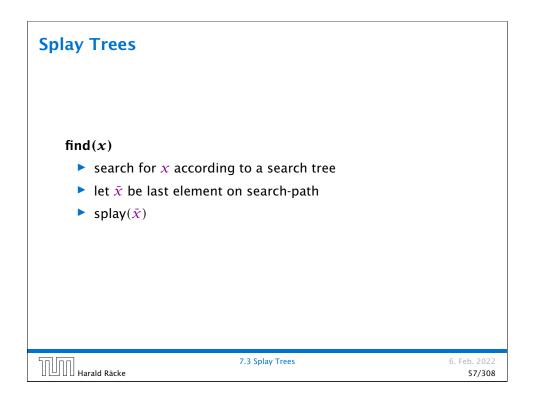

Disadvantage of balanced search trees:

- worst case; no advantage for easy inputs
- additional memory required
- complicated implementation

Splay Trees:

- + after access, an element is moved to the root; splay(x) repeated accesses are faster
- only amortized guarantee
- read-operations change the tree

<section-header>Acter as a covered in detail in Chapter 13 of [CLRS90]Model as a covered in detail in Chapter 13 of [CLRS90]Model as a covered in detail in Chapter 13 of [CLRS90]

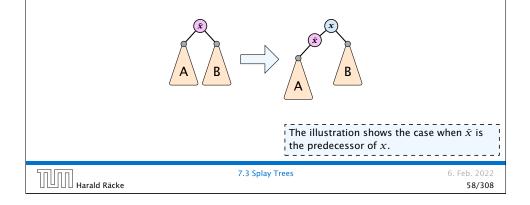

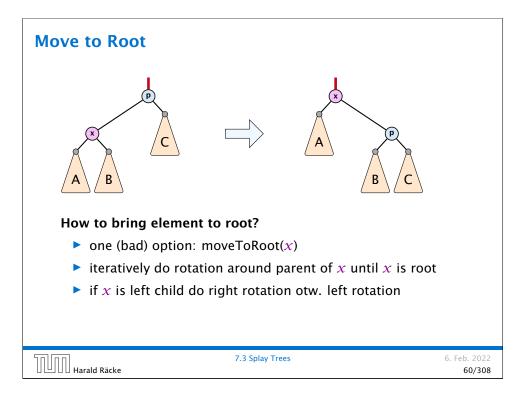

6. Feb. 2022 56/308

Splay Trees

insert(x)

- search for x; x̄ is last visited element during search (successer or predecessor of x)
- splay(\bar{x}) moves \bar{x} to the root
- insert x as new root

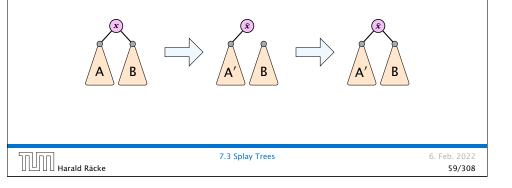

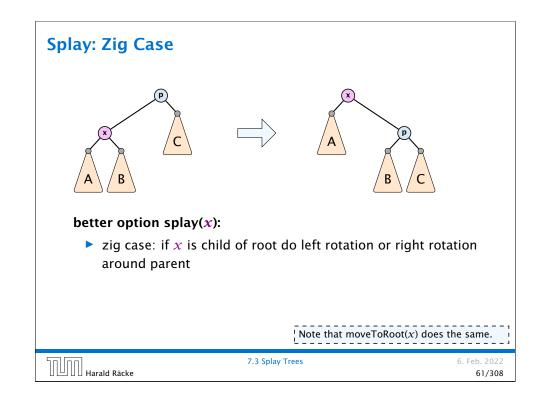

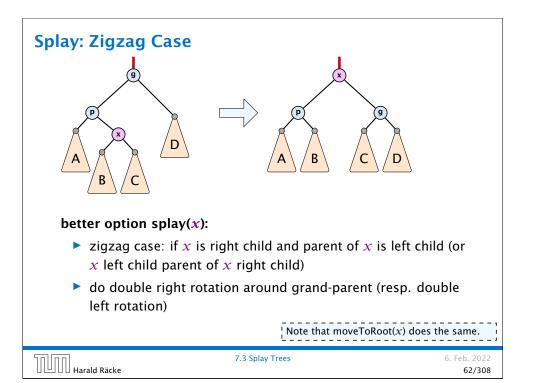

Splay Trees

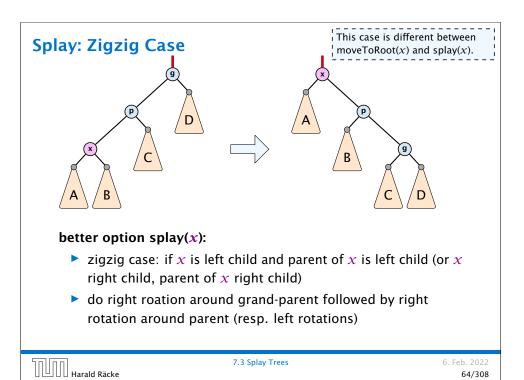

delete(x)

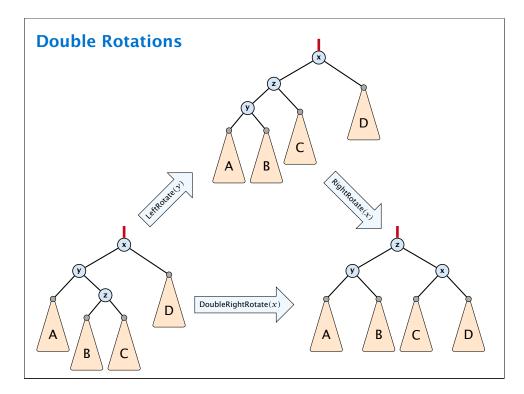

- search for x; splay(x); remove x
- search largest element \bar{x} in A
- splay(\bar{x}) (on subtree A)
- connect root of *B* as right child of \bar{x}

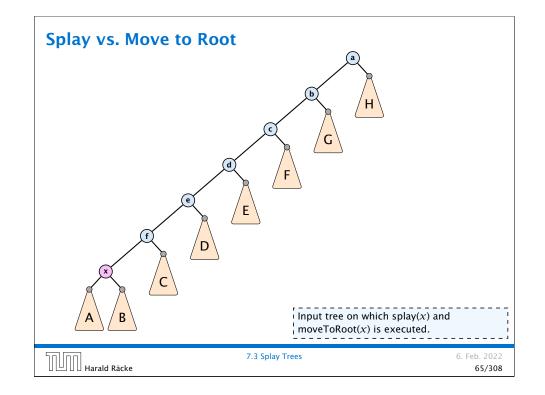

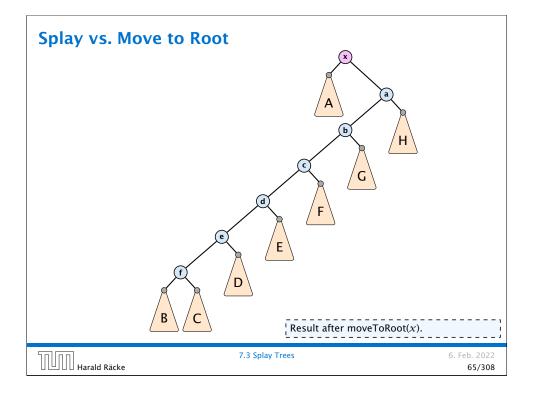

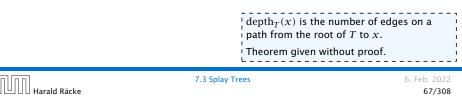

Static Optimality

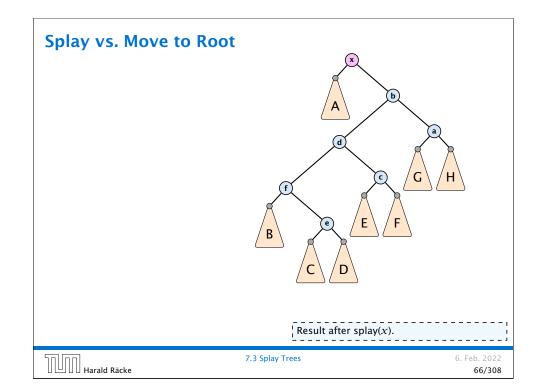

Suppose we have a sequence of m find-operations. find(x) appears h_x times in this sequence.

The cost of a static search tree *T* is:

$$cost(T) = m + \sum_{x} h_x \operatorname{depth}_T(x)$$

The total cost for processing the sequence on a splay-tree is $O(cost(T_{min}))$, where T_{min} is an optimal static search tree.

Dynamic Optimality	
 Let S be a sequence with m find-operations. Let A be a data-structure based on a search tree: the cost for accessing element x is 1 + depth(x); after accessing x the tree may be re-arranged through rotations; 	
Conjecture: A splay tree that only contains elements from <i>S</i> has cost $\mathcal{O}(cost(A, S))$, for processing <i>S</i> .	
7.3 Splay Trees	6. Feb. 2022 68/308

Lemma 5

Splay Trees have an amortized running time of $O(\log n)$ for all operations.

Harald Räcke	7.3 Splay Trees	6. Feb. 2022 69/308

Potential Method

Introduce a potential for the data structure.

- $\Phi(D_i)$ is the potential after the *i*-th operation.
- Amortized cost of the *i*-th operation is

$$\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) \ .$$

Show that $\Phi(D_i) \ge \Phi(D_0)$.

Then

$$\sum_{i=1}^{k} c_i \le \sum_{i=1}^{k} c_i + \Phi(D_k) - \Phi(D_0) = \sum_{i=1}^{k} \hat{c}_i$$

This means the amortized costs can be used to derive a bound on the total cost.

Harald Räcke

7.3 Splay Trees

6. Feb. 2022 71/308

Amortized Analysis

Definition 6

A data structure with operations $op_1(), \ldots, op_k()$ has amortized running times t_1, \ldots, t_k for these operations if the following holds.

Suppose you are given a sequence of operations (starting with an empty data-structure) that operate on at most n elements, and let k_i denote the number of occurences of $op_i()$ within this sequence. Then the actual running time must be at most $\sum_i k_i \cdot t_i(n)$.

> 6. Feb. 2022 70/308

7.3 Splay Trees

Example: Stack Stack ► S. push() ► S. pop() **S. multipop**(*k*): removes *k* items from the stack. If the stack currently contains less than k items it empties the stack. • The user has to ensure that pop and multipop do not generate an underflow. Actual cost: ► *S*. push(): cost 1. ► *S*. pop(): cost 1. • *S*. multipop(*k*): cost min{size, k} = *k*. Harald Räcke 7.3 Splay Trees 6. Feb. 2022 72/308

Example: Stack

Use potential function $\Phi(S)$ = number of elements on the stack. Amortized cost: ► S. push(): cost $\hat{C}_{\text{push}} = C_{\text{push}} + \Delta \Phi = 1 + 1 \le 2$. Note that the analysis becomes wrong if pop() or multipop() are called on an ► S. pop(): cost empty stack. $\hat{C}_{\text{pop}} = C_{\text{pop}} + \Delta \Phi = 1 - 1 \le 0 \ .$ ► S. multipop(k): cost $\hat{C}_{\rm mp} = C_{\rm mp} + \Delta \Phi = \min\{\text{size}, k\} - \min\{\text{size}, k\} \le 0$. 7.3 Splay Trees 6. Feb. 2022 Harald Räcke

Example: Binary Counter

Choose potential function $\Phi(x) = k$, where k denotes the number of ones in the binary representation of *x*.

Amortized cost:

Changing bit from 0 to 1:

$$\hat{C}_{0 \to 1} = C_{0 \to 1} + \Delta \Phi = 1 + 1 \le 2 .$$

Changing bit from 1 to 0:

$$\hat{C}_{1\to 0} = C_{1\to 0} + \Delta \Phi = 1 - 1 \le 0$$

 \blacktriangleright Increment: Let k denotes the number of consecutive ones in the least significant bit-positions. An increment involves k $(1 \rightarrow 0)$ -operations, and one $(0 \rightarrow 1)$ -operation.

Hence, the amortized cost is $k\hat{C}_{1\rightarrow 0} + \hat{C}_{0\rightarrow 1} \leq 2$.

Example: Binary Counter

Incrementing a binary counter:

Consider a computational model where each bit-operation costs one time-unit.

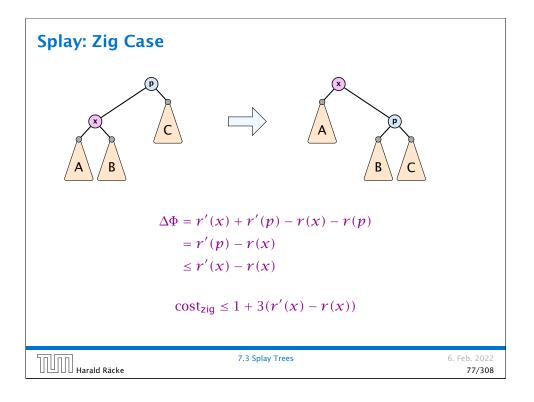

Incrementing an *n*-bit binary counter may require to examine *n*-bits, and maybe change them.

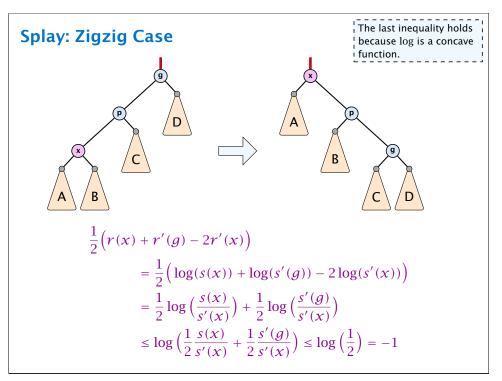

Actual cost:

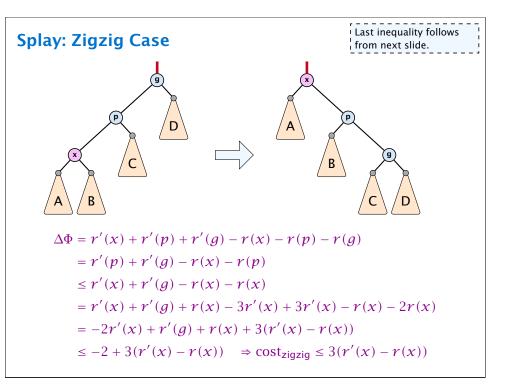

- ► Changing bit from 0 to 1: cost 1.
- ► Changing bit from 1 to 0: cost 1.
- Increment: cost is k + 1, where k is the number of consecutive ones in the least significant bit-positions (e.g. 001101 has k = 1).

7.4 Augmenting Data Structures

How to augment a data-structure

- 1. choose an underlying data-structure
- 2. determine additional information to be stored in the underlying structure
- **3.** verify/show how the additional information can be maintained for the basic modifying operations on the underlying structure.

4. develop the new operations

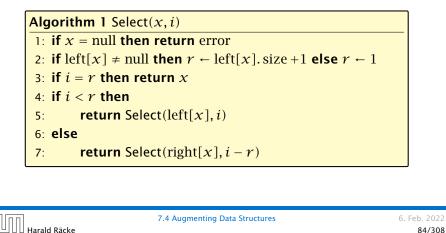

4. develop the new operations	 on each other. For example it makes no sense to choose additional information to be stored (Step 2), and later realize that either the information cannot be maintained efficiently (Step 3) or is not sufficient to support the new operations (Step 4). However, the above outline is a good way to describe/document a new data-structure.

7.5 Skip Lists

6. Feb. 2022 86/308

Why do we not use a list for implementing the ADT Dynamic Set?

- time for search $\Theta(n)$
- time for insert $\Theta(n)$ (dominated by searching the item)
- ► time for delete Θ(1) if we are given a handle to the object, otw. Θ(n)

↓ ·∞→5→8→10→12→14→18→23→26↔28↔35↔43↔∞

7.5 Skip Lists

Choose ratios between list-lengths evenly, i.e., $\frac{|L_{i-1}|}{|L_i|} = r$, and, hence, $L_k \approx r^{-k}n$.

Worst case running time is: $O(r^{-k}n + kr)$. Choose $r = n^{\frac{1}{k+1}}$. Then

$$\begin{aligned} r^{-k}n + kr &= \left(n^{\frac{1}{k+1}}\right)^{-k}n + kn^{\frac{1}{k+1}} \\ &= n^{1-\frac{k}{k+1}} + kn^{\frac{1}{k+1}} \\ &= (k+1)n^{\frac{1}{k+1}} \ . \end{aligned}$$

Choosing $k = \Theta(\log n)$ gives a logarithmic running time.

]]]]|]||| Harald Räcke

6. Feb. 2022 91/308

7.5 Skip Lists

Add more express lanes. Lane L_i contains roughly every $\frac{L_{i-1}}{L_i}$ -th item from list L_{i-1} .

Search(x) (k + 1 lists L_0, \ldots, L_k)

- Find the largest item in list L_k that is smaller than x. At most $|L_k| + 2$ steps.
- Find the largest item in list L_{k-1} that is smaller than x. At most $\left[\frac{|L_{k-1}|}{|L_{k}|+1}\right] + 2$ steps.
- Find the largest item in list L_{k-2} that is smaller than x. At most $\left[\frac{|L_{k-2}|}{|L_{k-1}|+1}\right] + 2$ steps.
- ▶ ...

• At most
$$|L_k| + \sum_{i=1}^k \frac{L_{i-1}}{L_i} + 3(k+1)$$
 steps.

Insert:

- A search operation gives you the insert position for element x in every list.
- ► Flip a coin until it shows head, and record the number t ∈ {1,2,...} of trials needed.
- lnsert x into lists L_0, \ldots, L_{t-1} .

Delete:

- > You get all predecessors via backward pointers.
- Delete x in all lists it actually appears in.

The time for both operations is dominated by the search time.

🛛 🛄 🔲 Harald Räcke		93/308

High Probability

Definition 7 (High Probability)

We say a **randomized** algorithm has running time $O(\log n)$ with high probability if for any constant α the running time is at most $O(\log n)$ with probability at least $1 - \frac{1}{n^{\alpha}}$.

Here the \mathcal{O} -notation hides a constant that may depend on α .

High Probability

Suppose there are polynomially many events $E_1, E_2, ..., E_\ell$, $\ell = n^c$ each holding with high probability (e.g. E_i may be the event that the *i*-th search in a skip list takes time at most $O(\log n)$).

Then the probability that all E_i hold is at least

$$\Pr[E_1 \wedge \cdots \wedge E_{\ell}] = 1 - \Pr[\bar{E}_1 \vee \cdots \vee \bar{E}_{\ell}]$$

$$\geq 1 - n^c \cdot n^{-\alpha}$$

$$= 1 - n^{c-\alpha} .$$

This means $\Pr[E_1 \land \cdots \land E_\ell]$ holds with high probability.

Harald Räcke

6. Feb. 2022 95/308

Lemma 8

A search (and, hence, also insert and delete) in a skip list with n elements takes time O(logn) with high probability (w. h. p.).

Estimation for Binomial Coefficients

 $\left(\frac{n}{k}\right)^{k} \le {\binom{n}{k}} \le \left(\frac{en}{k}\right)^{k}$ $\binom{n}{k} = \frac{n!}{k! \cdot (n-k)!} = \frac{n \cdot \dots \cdot (n-k+1)}{k \cdot \dots \cdot 1} \ge \left(\frac{n}{k}\right)^{k}$ $\binom{n}{k} = \frac{n \cdot \dots \cdot (n-k+1)}{k!} \le \frac{n^{k}}{k!} = \frac{n^{k} \cdot k^{k}}{k^{k} \cdot k!}$ $= \left(\frac{n}{k}\right)^{k} \cdot \frac{k^{k}}{k!} \le \left(\frac{n}{k}\right)^{k} \cdot \sum_{i \ge 0} \frac{k^{i}}{i!} = \left(\frac{en}{k}\right)^{k}$

7.5 Skip Lists Backward analysis: $\xrightarrow{23}$ \xrightarrow

- A "long" search path must also go very high.
- There are no elements in high lists.

From this it follows that w.h.p. there are no long paths.

החוחר	7.5 Skip Lists	6. Feb. 2022
Harald Räcke		98/308

7.5 Skip Lists

Let $E_{z,k}$ denote the event that a search path is of length z (number of edges) but does not visit a list above L_k .

In particular, this means that during the construction in the backward analysis we see at most k heads (i.e., coin flips that tell you to go up) in z trials.

 $\Pr[E_{z,k}] \leq \Pr[\text{at most } k \text{ heads in } z \text{ trials}]$

$$\leq \binom{z}{k} 2^{-(z-k)} \leq \left(\frac{ez}{k}\right)^k 2^{-(z-k)} \leq \left(\frac{2ez}{k}\right)^k 2^{-z}$$

choosing $k = \gamma \log n$ with $\gamma \ge 1$ and $z = (\beta + \alpha)\gamma \log n$

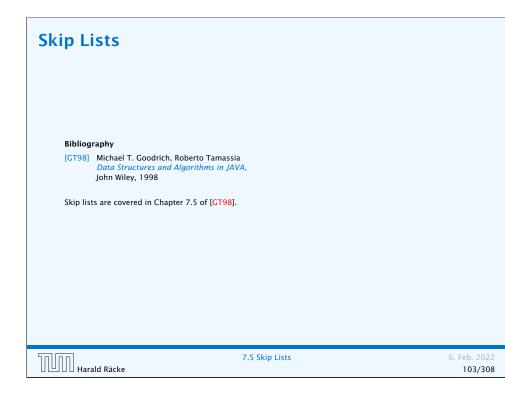

$$\leq \left(\frac{2ez}{k}\right)^{k} 2^{-\beta k} \cdot n^{-\gamma \alpha} \leq \left(\frac{2ez}{2^{\beta}k}\right)^{k} \cdot n^{-\alpha}$$
$$\leq \left(\frac{2e(\beta + \alpha)}{2^{\beta}}\right)^{k} n^{-\alpha}$$

now choosing $\beta = 6\alpha$ gives

$$\leq \left(\frac{42\alpha}{64^{lpha}}\right)^k n^{-lpha} \leq n^{-lpha}$$

for $\alpha \geq 1$.

7.5 Skip Lists

So far we fixed $k = \gamma \log n$, $\gamma \ge 1$, and $z = 7\alpha \gamma \log n$, $\alpha \ge 1$.

This means that a search path of length $\Omega(\log n)$ visits a list on a level $\Omega(\log n)$, w.h.p.

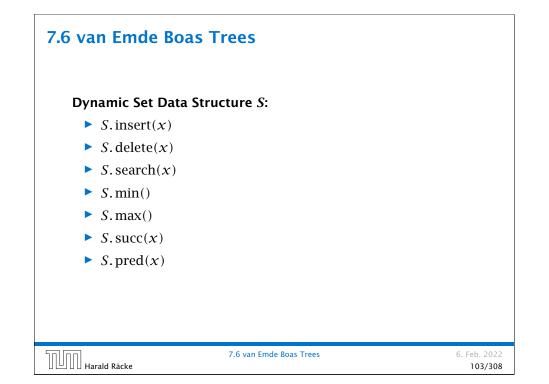

Let A_{k+1} denote the event that the list L_{k+1} is non-empty. Then

$\Pr[A_{k+1}] \le n2^{-(k+1)} \le n^{-(\gamma-1)}$.

For the search to take at least $z = 7\alpha \gamma \log n$ steps either the event $E_{z,k}$ or the event A_{k+1} must hold. Hence,

$$\begin{aligned} &\Pr[\text{search requires } z \text{ steps}] \leq \Pr[E_{z,k}] + \Pr[A_{k+1}] \\ &\leq n^{-\alpha} + n^{-(\gamma-1)} \end{aligned}$$

This means, the search requires at most z steps, w. h. p.

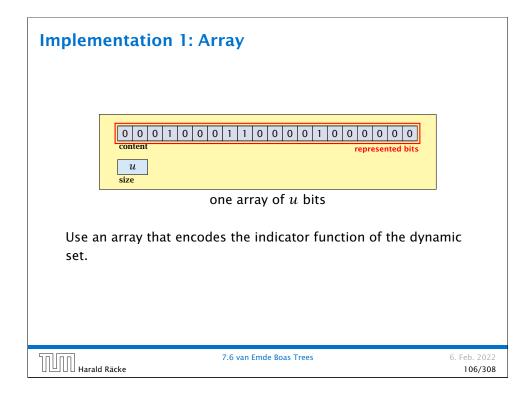

7.6 van Emde Boas Trees

For this chapter we ignore the problem of storing satellite data:

- ► *S*. insert(*x*): Inserts *x* into *S*.
- S. delete(x): Deletes x from S. Usually assumes that $x \in S$.
- S. member(x): Returns 1 if $x \in S$ and 0 otw.
- **S. min():** Returns the value of the minimum element in *S*.
- **S.** max(): Returns the value of the maximum element in *S*.
- S. succ(x): Returns successor of x in S. Returns null if x is maximum or larger than any element in S. Note that x needs not to be in S.
- S. pred(x): Returns the predecessor of x in S. Returns null if x is minimum or smaller than any element in S. Note that x needs not to be in S.

• Running time is $\mathcal{O}(u)$ in the worst case.

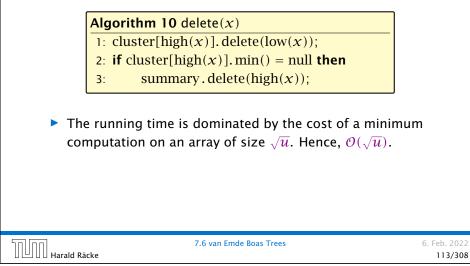

Harald Räcke	7.6 van Emde Boas Trees	

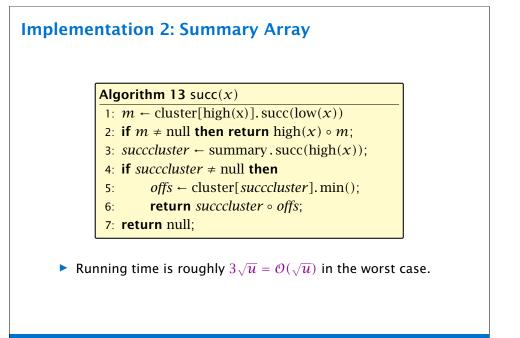

Implementation 2: Summary Array

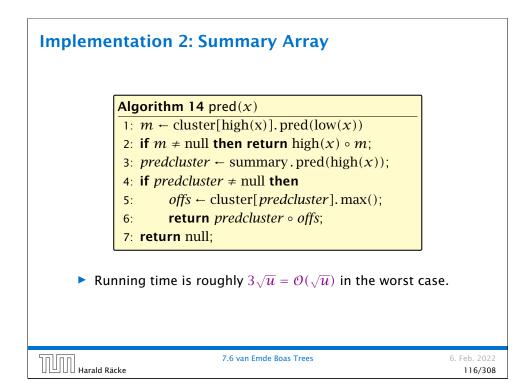

The bit for a key x is contained in cluster number $\left|\frac{x}{\sqrt{y}}\right|$. Within the cluster-array the bit is at position $x \mod \sqrt{u}$. For simplicity we assume that $u = 2^{2k}$ for some $k \ge 1$. Then we can compute the cluster-number for an entry x as high(x) (the upper half of the dual representation of x) and the position of xwithin its cluster as low(x) (the lower half of the dual representation). 7.6 van Emde Boas Trees 6. Feb. 2022 Harald Räcke

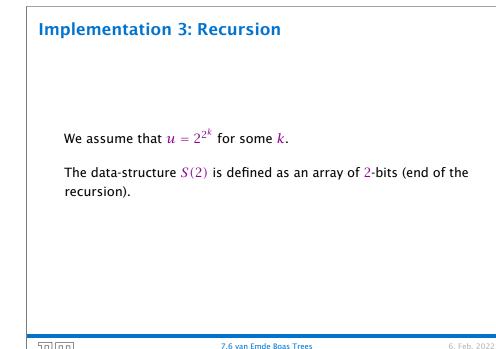

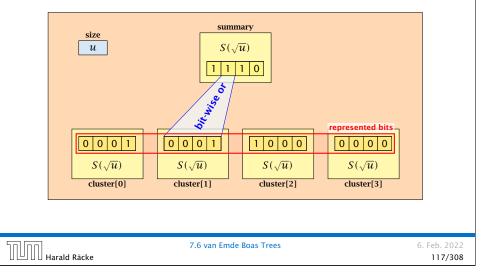

Harald Räcke

Implementation 3: Recursion

Instead of using sub-arrays, we build a recursive data-structure.

S(u) is a dynamic set data-structure representing u bits:

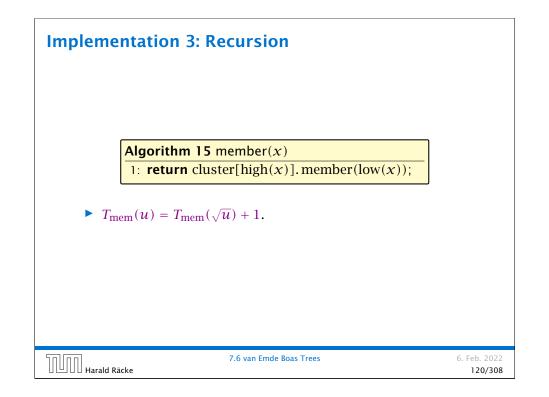

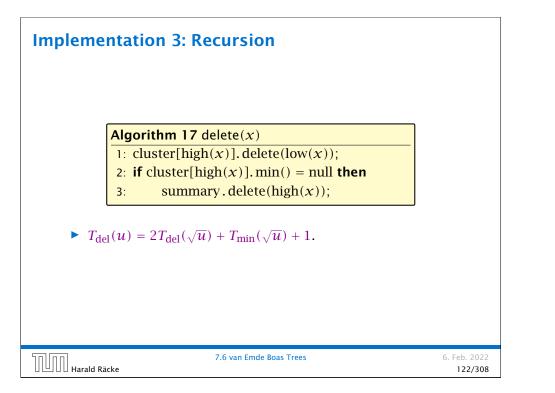

Implementation 3: Recursion

The code from Implementation 2 can be used unchanged. We only need to redo the analysis of the running time.

Note that in the code we do not need to specifically address the non-recursive case. This is achieved by the fact that an S(4) will contain S(2)'s as sub-datastructures, which are arrays. Hence, a call like cluster[1].min() from within the data-structure S(4) is not a recursive call as it will call the function array.min().

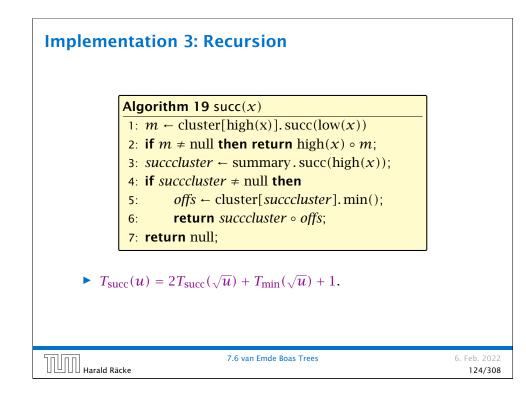

This means that the non-recursive case is been dealt with while initializing the data-structure.

Impleme	ntation 3: Recursion	
	Algorithm 16 insert(x)1: cluster[high(x)].insert(low(x));2: summary.insert(high(x));	
► T _{in}	$s(u) = 2T_{\rm ins}(\sqrt{u}) + 1.$	
Harald Ra	7.6 van Emde Boas Trees icke	6. Feb. 2022 121/308

	Algorithm 18 min() 1: mincluster ← summary.min();	
	2: if <i>mincluster</i> = null return null;	
	3: offs \leftarrow cluster[mincluster].min();	
	4: return <i>mincluster</i> ∘ <i>offs</i> ;	
•	$T_{\min}(u) = 2T_{\min}(\sqrt{u}) + 1.$	

Implementation 3: Recursion $T_{ins}(u) = 2T_{ins}(\sqrt{u}) + 1.$ Set $\ell := \log u$ and $X(\ell) := T_{ins}(2^{\ell})$. Then $X(\ell) = T_{ins}(2^{\ell}) = T_{ins}(u) = 2T_{ins}(\sqrt{u}) + 1$ $= 2T_{ins}(2^{\frac{\ell}{2}}) + 1 = 2X(\frac{\ell}{2}) + 1$.Using Master theorem gives $X(\ell) = \mathcal{O}(\ell)$, and hence $T_{ins}(u) = \mathcal{O}(\log u).$ The same holds for $T_{max}(u)$ and $T_{min}(u).$

|||||||| Harald Räcke

7.6 van Emde Boas Trees

Implementation 3: Recursion

 $T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1:$

Set $\ell := \log u$ and $X(\ell) := T_{\text{mem}}(2^{\ell})$. Then

$$X(\ell) = T_{\text{mem}}(2^{\ell}) = T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$$
$$= T_{\text{mem}}(2^{\frac{\ell}{2}}) + 1 = X(\frac{\ell}{2}) + 1 .$$

Using Master theorem gives $X(\ell) = O(\log \ell)$, and hence $T_{\text{mem}}(u) = O(\log \log u)$.

Harald Räcke

7.6 van Emde Boas Trees

```
Implementation 3: Recursion

T_{del}(u) = 2T_{del}(\sqrt{u}) + T_{min}(\sqrt{u}) + 1 \le 2T_{del}(\sqrt{u}) + c \log(u).
Set \ell := \log u and X(\ell) := T_{del}(2^{\ell}). Then

X(\ell) = T_{del}(2^{\ell}) = T_{del}(u) = 2T_{del}(\sqrt{u}) + c \log u
= 2T_{del}(2^{\frac{\ell}{2}}) + c\ell = 2X(\frac{\ell}{2}) + c\ell .
Using Master theorem gives X(\ell) = \Theta(\ell \log \ell), and hence

T_{del}(u) = O(\log u \log \log u).

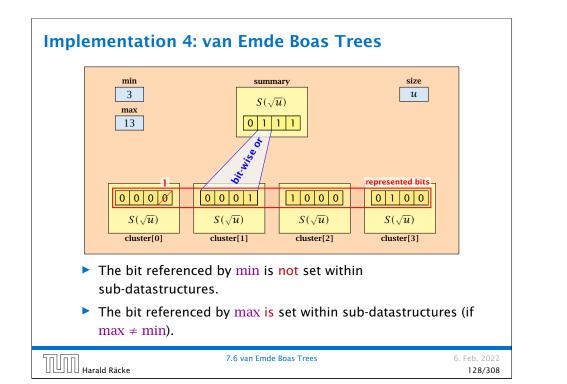

The same holds for T_{pred}(u) and T_{succ}(u).
```

Constant	ant time.	
Harald Räcke	7.6 van Emde Boas Trees	6. Feb. 2022 130/308

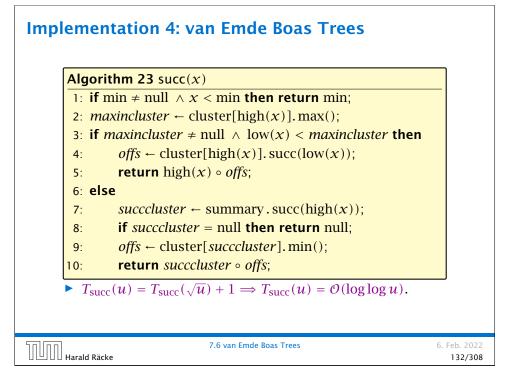

Implementation 4: van Emde Boas Trees

Advantages of having max/min pointers:

- Recursive calls for min and max are constant time.
- min = null means that the data-structure is empty.
- min = max ≠ null means that the data-structure contains exactly one element.
- We can insert into an empty datastructure in constant time by only setting min = max = x.
- We can delete from a data-structure that just contains one element in constant time by setting min = max = null.

7.6 van Emde Boas Trees

Space requirements:

The space requirement fulfills the recurrence

$S(u) = (\sqrt{u} + 1)S(\sqrt{u}) + \mathcal{O}(\sqrt{u}) .$

- Note that we cannot solve this recurrence by the Master theorem as the branching factor is not constant.
- One can show by induction that the space requirement is S(u) = O(u). Exercise.

Implementation 4: van Emde Boas Trees

Note that only one of the possible recusive calls in Line 9 and Line 11 in the deletion-algorithm may take non-constant time.

To see this observe that the call in Line 11 only occurs if the cluster where x was deleted is now empty. But this means that the call in Line 9 deleted the last element in cluster[high(x)]. Such a call only takes constant time.

Hence, we get a recurrence of the form

$$T_{\rm del}(u) = T_{\rm del}(\sqrt{u}) + c$$
.

This gives $T_{del}(u) = O(\log \log u)$.

Let the "real" recurrence relation be

 $S(k^2) = (k+1)S(k) + c_1 \cdot k; S(4) = c_2$

• Replacing S(k) by $R(k) := S(k)/c_2$ gives the recurrence

 $R(k^2) = (k+1)R(k) + ck; R(4) = 1$

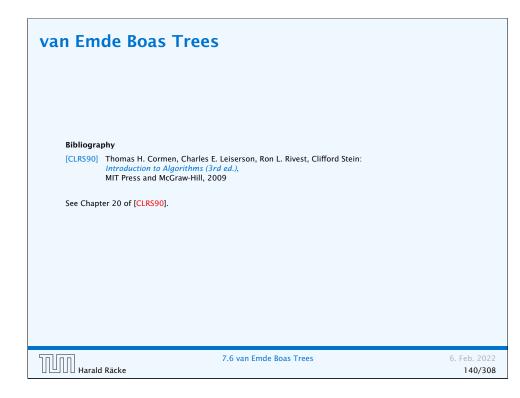

where $c = c_1/c_2 < 1$.

- Now, we show $R(k) \le k 2$ for squares $k \ge 4$.
 - Obviously, this holds for k = 4.
 - For $k = \ell^2 > 4$ with ℓ integral we have

$$\begin{split} R(k) &= (1+\ell)R(\ell) + c\ell \\ &\leq (1+\ell)(\ell-2) + \ell \leq k-2 \end{split}$$

This shows that R(k) and, hence, S(k) grows linearly.

7.7 Hashing

Definitions:

- Universe U of keys, e.g., $U \subseteq \mathbb{N}_0$. U very large.
- Set $S \subseteq U$ of keys, $|S| = m \le |U|$.
- Array T[0, ..., n-1] hash-table.
- Hash function $h: U \rightarrow [0, ..., n-1]$.

The hash-function *h* should fulfill:

- Fast to evaluate.
- Small storage requirement.
- Good distribution of elements over the whole table.

7.7 Hashing

Dictionary:

- S. insert(x): Insert an element x.
- ► *S*. delete(*x*): Delete the element pointed to by *x*.
- S. search(k): Return a pointer to an element e with key[e] = k in S if it exists; otherwise return null.

So far we have implemented the search for a key by carefully choosing split-elements.

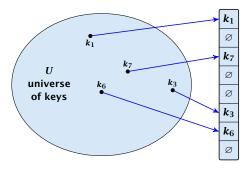

Then the memory location of an object x with key k is determined by successively comparing k to split-elements.

Hashing tries to directly compute the memory location from the given key. The goal is to have constant search time.

החוחר	7.7 Hashing	6. Feb. 2022
UUU Harald Räcke		140/308

Direct Addressing

Ideally the hash function maps all keys to different memory locations.

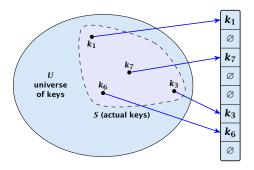

This special case is known as Direct Addressing. It is usually very unrealistic as the universe of keys typically is quite large, and in particular larger than the available memory.

6. Feb. 2022 141/308

Perfect Hashing

Suppose that we know the set S of actual keys (no insert/no delete). Then we may want to design a simple hash-function that maps all these keys to different memory locations.

Such a hash function h is called a perfect hash function for set S.

Harald Räcke	7.7 Hashing	6. Feb. 2022 143/308

Collisions

Typically, collisions do not appear once the size of the set S of actual keys gets close to n, but already when $|S| \ge \omega(\sqrt{n})$.

Lemma 9

The probability of having a collision when hashing m elements into a table of size n under uniform hashing is at least

 $1 - e^{-\frac{m(m-1)}{2n}} \approx 1 - e^{-\frac{m^2}{2n}}$.

Uniform hashing:

Choose a hash function uniformly at random from all functions $f: U \rightarrow [0, \dots, n-1]$.

Collisions

If we do not know the keys in advance, the best we can hope for is that the hash function distributes keys evenly across the table.

Problem: Collisions

Usually the universe U is much larger than the table-size n.

Hence, there may be two elements k_1, k_2 from the set *S* that map to the same memory location (i.e., $h(k_1) = h(k_2)$). This is called a collision.

Harald Räcke	7.7 Hashing

Collisions

٦

Proof.

F

Let $A_{m,n}$ denote the event that inserting m keys into a table of size n does not generate a collision. Then

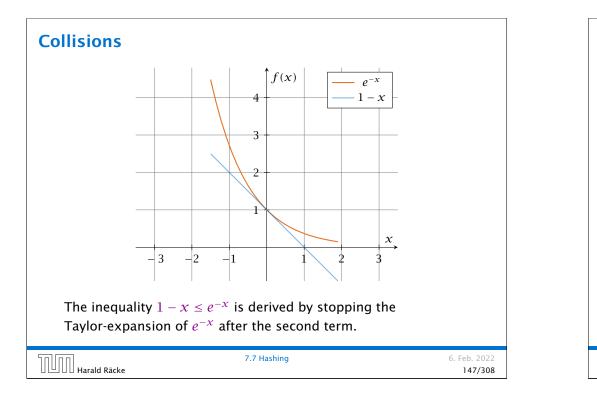

$$\Pr[A_{m,n}] = \prod_{\ell=1}^{m} \frac{n-\ell+1}{n} = \prod_{j=0}^{m-1} \left(1 - \frac{j}{n}\right)$$
$$\leq \prod_{j=0}^{m-1} e^{-j/n} = e^{-\sum_{j=0}^{m-1} \frac{j}{n}} = e^{-\frac{m(m-1)}{2n}} .$$

Here the first equality follows since the ℓ -th element that is hashed has a probability of $\frac{n-\ell+1}{n}$ to not generate a collision under the condition that the previous elements did not induce collisions.

6. Feb. 2022 144/308

7.7 Hashing

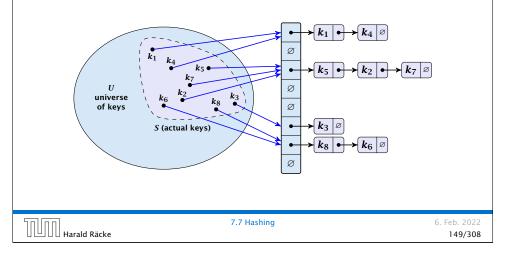

6. Feb. 2022 145/308

Hashing with Chaining

Arrange elements that map to the same position in a linear list.

- Access: compute h(x) and search list for key[x].
- Insert: insert at the front of the list.

Resolving Collisions

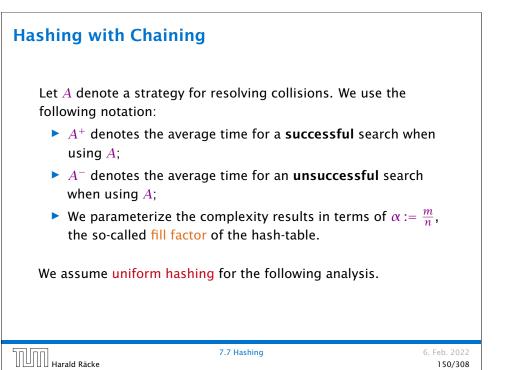

The methods for dealing with collisions can be classified into the two main types

- open addressing, aka. closed hashing
- hashing with chaining, aka. closed addressing, open hashing.

There are applications e.g. computer chess where you do not resolve collisions at all.

 7.7 Hashing
 6. Feb. 2022

 Harald Räcke
 148/308

Hashing with Chaining

The time required for an unsuccessful search is 1 plus the length of the list that is examined. The average length of a list is $\alpha = \frac{m}{n}$. Hence, if A is the collision resolving strategy "Hashing with Chaining" we have

 $A^- = 1 + \alpha .$

Harald Räcke	7.7 Hashing	6. Feb. 2022 151/308

Hashing with Chaining

$$E\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right] = \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}E\left[X_{ij}\right]\right)$$

$$= \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}\frac{1}{n}\right)$$

$$= 1+\frac{1}{mn}\sum_{i=1}^{m}(m-i)$$

$$= 1+\frac{1}{mn}\left(m^{2}-\frac{m(m+1)}{2}\right)$$

$$= 1+\frac{m-1}{2n} = 1+\frac{\alpha}{2}-\frac{\alpha}{2m}$$
Hence, the expected cost for a successful search is $A^{+} \le 1+\frac{\alpha}{2}$.

Hashing with Chaining

For a successful search observe that we do **not** choose a list at random, but we consider a random key k in the hash-table and ask for the search-time for k.

This is 1 plus the number of elements that lie before *k* in *k*'s list.

Let k_{ℓ} denote the ℓ -th key inserted into the table.

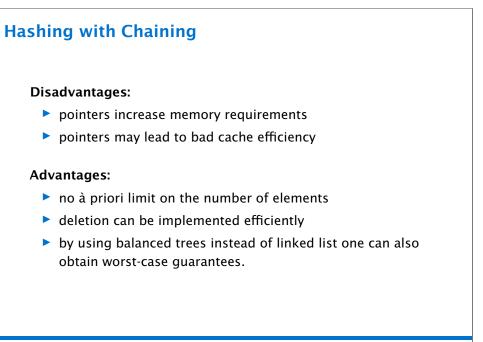

Let for two keys k_i and k_j , X_{ij} denote the indicator variable for the event that k_i and k_j hash to the same position. Clearly, $\Pr[X_{ii} = 1] = 1/n$ for uniform hashing.

The expected successful search cost is keys before k_i

 $\mathbf{E}\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right]$ cost for key k

7.7 Hashing

הח הר		
	Harald	Räcke

Harald Räcke

6. Feb. 2022 152/308

Open Addressing

All objects are stored in the table itself.

Define a function h(k, j) that determines the table-position to be examined in the *j*-th step. The values $h(k, 0), \ldots, h(k, n-1)$ must form a permutation of $0, \ldots, n-1$.

Search(*k*): Try position h(k, 0); if it is empty your search fails; otw. continue with h(k, 1), h(k, 2),

Insert(x): Search until you find an empty slot; insert your element there. If your search reaches h(k, n - 1), and this slot is non-empty then your table is full.

Harald Räcke		

7.7 Hashing

6. Feb. 2022 155/308

6. Feb. 2022

157/308

Linear Probing

- Advantage: Cache-efficiency. The new probe position is very likely to be in the cache.
- Disadvantage: Primary clustering. Long sequences of occupied table-positions get longer as they have a larger probability to be hit. Furthermore, they can merge forming larger sequences.

Lemma 10

Let L be the method of linear probing for resolving collisions:

$$L^{+} \approx \frac{1}{2} \left(1 + \frac{1}{1 - \alpha} \right)$$
$$L^{-} \approx \frac{1}{2} \left(1 + \frac{1}{(1 - \alpha)^{2}} \right)$$

7.7 Hashing

Open Addressing

Choices for h(k, j):

- Linear probing: h(k, i) = h(k) + i mod n (sometimes: h(k, i) = h(k) + ci mod n).
- Quadratic probing: $h(k, i) = h(k) + c_1 i + c_2 i^2 \mod n.$
- Double hashing: $h(k, i) = h_1(k) + ih_2(k) \mod n.$

For quadratic probing and double hashing one has to ensure that the search covers all positions in the table (i.e., for double hashing $h_2(k)$ must be relatively prime to n (teilerfremd); for quadratic probing c_1 and c_2 have to be chosen carefully).

החוהר	7.7 Hashing	6. Feb. 2022
UUU Harald Räcke		156/308

Quadratic Probing

- Not as cache-efficient as Linear Probing.
- Secondary clustering: caused by the fact that all keys mapped to the same position have the same probe sequence.

Lemma 11

Let Q be the method of quadratic probing for resolving collisions:

$$Q^{+} \approx 1 + \ln\left(\frac{1}{1-\alpha}\right) - \frac{\alpha}{2}$$
$$Q^{-} \approx \frac{1}{1-\alpha} + \ln\left(\frac{1}{1-\alpha}\right) - \alpha$$

Harald Räcke

7.7 Hashing

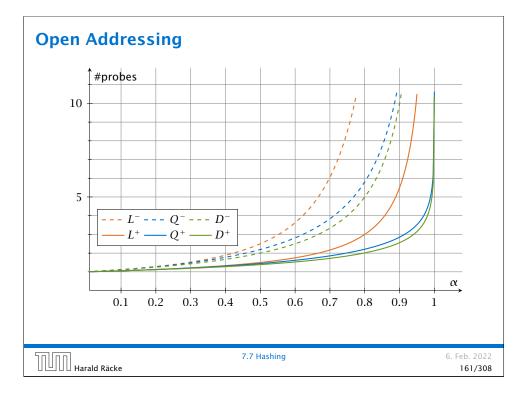

Double Hashing

• Any probe into the hash-table usually creates a cache-miss.

Lemma 12

Let D be the method of double hashing for resolving collisions:

$$D^{+} \approx \frac{1}{\alpha} \ln \left(\frac{1}{1 - \alpha} \right)$$
$$D^{-} \approx \frac{1}{1 - \alpha}$$
$$D^{-} \approx \frac{1}{1 - \alpha}$$

Analysis of Idealized Open Address Hashing We analyze the time for a search in a very idealized Open Addressing scheme. • The probe sequence h(k, 0), h(k, 1), h(k, 2), ... is equally likely to be any permutation of $\langle 0, 1, ..., n - 1 \rangle$. • The probe sequence h(k, 0), h(k, 1), h(k, 2), ... is equally likely to be any permutation of $\langle 0, 1, ..., n - 1 \rangle$.

Analysis of Idealized Open Address Hashing

Let X denote a random variable describing the number of probes in an unsuccessful search.

Let A_i denote the event that the *i*-th probe occurs and is to a non-empty slot.

$$\begin{split} \Pr[A_1 \cap A_2 \cap \dots \cap A_{i-1}] &= \Pr[A_1] \cdot \Pr[A_2 \mid A_1] \cdot \Pr[A_3 \mid A_1 \cap A_2] \cdot \\ \dots \cdot \Pr[A_{i-1} \mid A_1 \cap \dots \cap A_{i-2}] \end{split}$$
$$\Pr[X \ge i] &= \frac{m}{n} \cdot \frac{m-1}{n-1} \cdot \frac{m-2}{n-2} \cdot \dots \cdot \frac{m-i+2}{n-i+2} \\ &\leq \left(\frac{m}{n}\right)^{i-1} = \alpha^{i-1} \end{split}$$

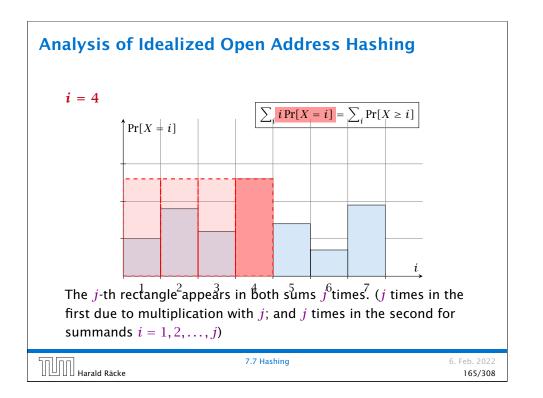

Analysis of Idealized Open Address Hashing

$$\mathbb{E}[X] = \sum_{i=1}^{\infty} \Pr[X \ge i] \le \sum_{i=1}^{\infty} \alpha^{i-1} = \sum_{i=0}^{\infty} \alpha^i = \frac{1}{1-\alpha} .$$

$$\frac{1}{1-\alpha} = 1 + \alpha + \alpha^2 + \alpha^3 + \dots$$

Analysis of Idealized Open Address Hashing

The number of probes in a successful search for k is equal to the number of probes made in an unsuccessful search for k at the time that k is inserted.

Let *k* be the i + 1-st element. The expected time for a search for *k* is at most $\frac{1}{1-i/n} = \frac{n}{n-i}$.

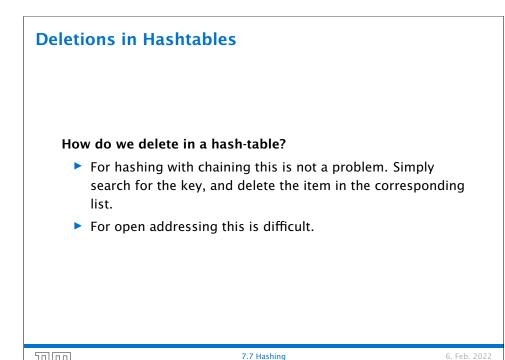

$$\frac{1}{m} \sum_{i=0}^{m-1} \frac{n}{n-i} = \frac{n}{m} \sum_{i=0}^{m-1} \frac{1}{n-i} = \frac{1}{\alpha} \sum_{k=n-m+1}^{n} \frac{1}{k}$$
$$\leq \frac{1}{\alpha} \int_{n-m}^{n} \frac{1}{x} dx = \frac{1}{\alpha} \ln \frac{n}{n-m} = \frac{1}{\alpha} \ln \frac{1}{1-\alpha} .$$

Harald Räcke

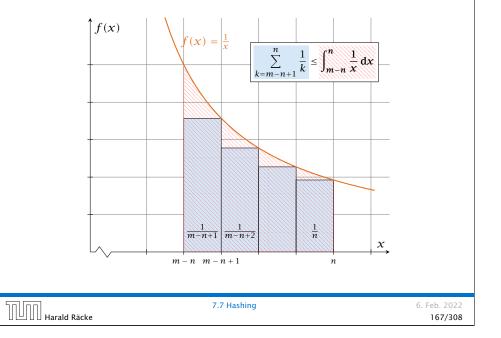

Harald Räcke

166/308

168/308

Analysis of Idealized Open Address Hashing

Deletions in Hashtables

- Simply removing a key might interrupt the probe sequence of other keys which then cannot be found anymore.
- One can delete an element by replacing it with a deleted-marker.
 - During an insertion if a deleted-marker is encountered an element can be inserted there.
 - During a search a deleted-marker must not be used to terminate the probe sequence.
- The table could fill up with deleted-markers leading to bad performance.
- ▶ If a table contains many deleted-markers (linear fraction of the keys) one can rehash the whole table and amortize the cost for this rehash against the cost for the deletions.

Deletions for Linear Probing

- For Linear Probing one can delete elements without using deletion-markers.
- Upon a deletion elements that are further down in the probe-sequence may be moved to guarantee that they are still found during a search.

Universal Hashing

Regardless, of the choice of hash-function there is always an input (a set of keys) that has a very poor worst-case behaviour.

Therefore, so far we assumed that the hash-function is random so that regardless of the input the average case behaviour is good.

However, the assumption of uniform hashing that h is chosen randomly from all functions $f: U \rightarrow [0, ..., n-1]$ is clearly unrealistic as there are $n^{|U|}$ such functions. Even writing down such a function would take $|U| \log n$ bits.

Universal hashing tries to define a set \mathcal{H} of functions that is much smaller but still leads to good average case behaviour when selecting a hash-function uniformly at random from \mathcal{H} .

Deletions for Linear Probing

Alg	gorithm 37 delete(p)
1:	$T[p] \leftarrow \text{null}$
2:	$p \leftarrow \operatorname{succ}(p)$
3:	while $T[p] \neq \text{null } \mathbf{do}$
4:	$\mathcal{Y} \leftarrow T[p]$
5:	$T[p] \leftarrow \text{null}$
6:	$p \leftarrow \operatorname{succ}(p)$
7:	$\operatorname{insert}(\gamma)$

 \ensuremath{p} is the index into the table-cell that contains the object to be deleted.

Pointers into the hash-table become invalid.

Universal Hashing

Definition 13

A class \mathcal{H} of hash-functions from the universe U into the set $\{0, \ldots, n-1\}$ is called universal if for all $u_1, u_2 \in U$ with $u_1 \neq u_2$

$$\Pr[h(u_1) = h(u_2)] \le \frac{1}{n}$$

where the probability is w.r.t. the choice of a random hash-function from set $\mathcal{H}.$

Note that this means that the probability of a collision between two arbitrary elements is at most $\frac{1}{n}$.

Definition 14

A class \mathcal{H} of hash-functions from the universe U into the set $\{0, \ldots, n-1\}$ is called 2-independent (pairwise independent) if the following two conditions hold

- For any key $u \in U$, and $t \in \{0, ..., n-1\}$ $\Pr[h(u) = t] = \frac{1}{n}$, i.e., a key is distributed uniformly within the hash-table.
- For all $u_1, u_2 \in U$ with $u_1 \neq u_2$, and for any two hash-positions t_1, t_2 :

 $\Pr[h(u_1) = t_1 \wedge h(u_2) = t_2] \le \frac{1}{n^2} .$

This requirement clearly implies a universal hash-function.

]]][]]| Harald Räcke 7.7 Hashing

Universal Hashing

There is a one-to-one correspondence between hash-functions (pairs (a, b), $a \neq 0$) and pairs (t_x, t_y) , $t_x \neq t_y$.

Therefore, we can view the first step (before the mod *n*-operation) as choosing a pair (t_x, t_y) , $t_x \neq t_y$ uniformly at random.

What happens when we do the mod n operation?

Fix a value t_x . There are p - 1 possible values for choosing t_y .

From the range 0, ..., p - 1 the values $t_x, t_x + n, t_x + 2n, ...$ map to t_x after the modulo-operation. These are at most $\lceil p/n \rceil$ values.

Universal Hashing

The hash-function does not generate collisions before the (mod n)-operation. Furthermore, every choice (a, b) is mapped to a different pair (t_x, t_y) with t_x := ax + b and t_y := ay + b.

This holds because we can compute *a* and *b* when given t_x and t_y :

$t_x \equiv ax + b$	$(\mod p)$
$t_{\mathcal{Y}} \equiv a \mathcal{Y} + b$	$(\mod p)$
$t_x - t_y \equiv a(x - y)$	$(\mod p)$
$t_{\mathcal{Y}} \equiv ay + b$	$(\mod p)$
$a \equiv (t_x - t_y)(x - y)^{-1}$	$(\mod p)$
$b \equiv t_{\mathcal{Y}} - a_{\mathcal{Y}}$	$(\mod p)$

Universal Hashing
As $t_{\mathcal{Y}} \neq t_{\mathcal{X}}$ there are
$\left\lceil \frac{p}{n} \right\rceil - 1 \le \frac{p}{n} + \frac{n-1}{n} - 1 \le \frac{p-1}{n}$
possibilities for choosing $t_{\mathcal{Y}}$ such that the final hash-value creates a collision.
This happens with probability at most $\frac{1}{n}$.

Harald Räcke

6. Feb. 2022 180/308

6. Feb. 2022 178/308

It is also possible to show that ${\mathcal H}$ is an (almost) pairwise independent class of hash-functions.

$$\frac{\left\lfloor \frac{p}{n} \right\rfloor^2}{p(p-1)} \leq \Pr_{t_x \neq t_y \in \mathbb{Z}_p^2} \left[\begin{array}{c} t_x \bmod n = h_1 \\ t_y \bmod n = h_2 \end{array} \right] \leq \frac{\left\lceil \frac{p}{n} \right\rceil^2}{p(p-1)}$$

Note that the middle is the probability that $h(x) = h_1$ and $h(y) = h_2$. The total number of choices for (t_x, t_y) is p(p-1). The number of choices for t_x (t_y) such that $t_x \mod n = h_1$ $(t_y \mod n = h_2)$ lies between $\lfloor \frac{p}{n} \rfloor$ and $\lceil \frac{p}{n} \rceil$.

6. Feb. 2022 186/308

Perfect Hashing

Suppose that we **know** the set *S* of actual keys (no insert/no delete). Then we may want to design a **simple** hash-function that maps all these keys to different memory locations.

Universal Hashing

Therefore the probability of choosing $h_{\tilde{a}}$ from A_{ℓ} is only

$$\begin{split} \frac{\lceil \frac{q}{n} \rceil^{\ell} \cdot q^{d-\ell+1}}{q^{d+1}} &\leq \frac{(\frac{q+n}{n})^{\ell}}{q^{\ell}} \leq \left(\frac{q+n}{q}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \\ &\leq \left(1 + \frac{1}{\ell}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \leq \frac{e}{n^{\ell}} \end{split}$$

This shows that the \mathcal{H} is (e, d + 1)-universal.

The last step followed from $q \ge (d+1)n$, and $\ell \le d+1$.

🛛 💾 🛛 🖓 Harald Räcke		187/308

Perfect Hashing

Let m = |S|. We could simply choose the hash-table size very large so that we don't get any collisions.

Using a universal hash-function the expected number of collisions is

 $\mathbf{E}[\texttt{#Collisions}] = \binom{m}{2} \cdot \frac{1}{n} \ .$

If we choose $n = m^2$ the expected number of collisions is strictly less than $\frac{1}{2}$.

Can we get an upper bound on the probability of having collisions?

The probability of having 1 or more collisions can be at most $\frac{1}{2}$ as otherwise the expectation would be larger than $\frac{1}{2}$.

Harald Räcke

Perfect Hashing

We can find such a hash-function by a few trials.

However, a hash-table size of $n = m^2$ is very very high.

We construct a two-level scheme. We first use a hash-function that maps elements from S to m buckets.

Let m_j denote the number of items that are hashed to the *j*-th bucket. For each bucket we choose a second hash-function that maps the elements of the bucket into a table of size m_j^2 . The second function can be chosen such that all elements are mapped to different locations.

Harald Räcke	

7.7 Hashing

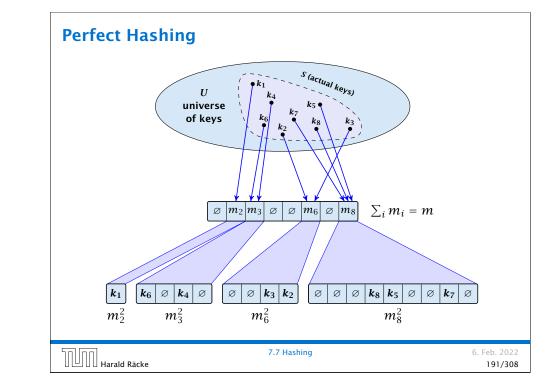

Perfect Hashing

The total memory that is required by all hash-tables is $\mathcal{O}(\sum_j m_j^2)$. Note that m_j is a random variable.

$\mathbf{E}\left[\sum_{j} m_{j}^{2}\right] = \mathbf{E}\left[2\sum_{j} \binom{m_{j}}{2} + \sum_{j} m_{j}\right]$
$= 2 \operatorname{E}\left[\sum_{j} \binom{m_{j}}{2}\right] + \operatorname{E}\left[\sum_{j} m_{j}\right]$

The first expectation is simply the expected number of collisions, for the first level. Since we use universal hashing we have

$$= 2\binom{m}{2}\frac{1}{m} + m = 2m - 1$$

Perfect Hashing

Harald Räcke

We need only $\mathcal{O}(m)$ time to construct a hash-function h with $\sum_j m_j^2 = \mathcal{O}(4m)$, because with probability at least 1/2 a random function from a universal family will have this property.

Then we construct a hash-table h_j for every bucket. This takes expected time $\mathcal{O}(m_j)$ for every bucket. A random function h_j is collision-free with probability at least 1/2. We need $\mathcal{O}(m_j)$ to test this.

We only need that the hash-functions are chosen from a universal family!!!

Cuckoo Hashing

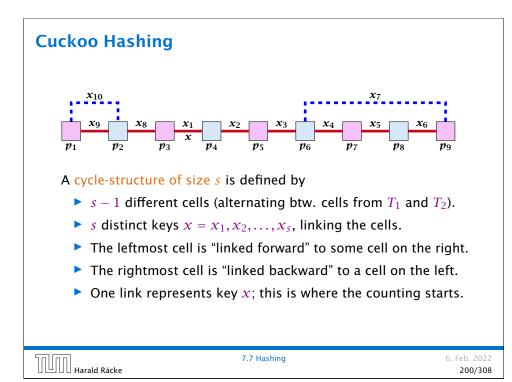

Cuckoo Hashing We call one iteration through the while-loop a step of the algorithm. We call a sequence of iterations through the while-loop without the termination condition becoming true a phase of the algorithm. We say a phase is successful if it is not terminated by the maxstep-condition, but the while loop is left because x = null.

What is the expected time for an insert-operation?

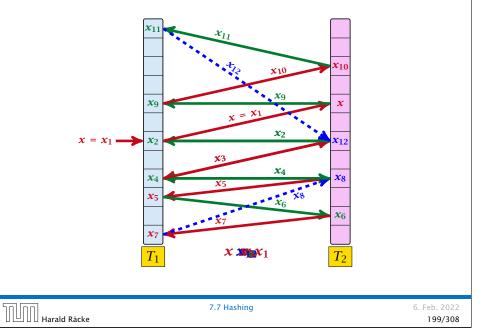

We first analyze the probability that we end-up in an infinite loop (that is then terminated after maxsteps steps).

Formally what is the probability to enter an infinite loop that touches *s* different keys?

Harald Räcke	7.7 Hashing	6. Feb. 2022 198/308

Cuckoo Hashing: Insert

Cuckoo Hashing A cycle-structure is active if for every key x_{ℓ} (linking a cell p_i from T_1 and a cell p_j from T_2) we have $h_1(x_{\ell}) = p_i$ and $h_2(x_{\ell}) = p_j$

Observation:

If during a phase the insert-procedure runs into a cycle there must exist an active cycle structure of size $s \ge 3$.

What is the probability that all keys in a cycle-structure of size s correctly map into their T_1 -cell?

This probability is at most $\frac{\mu}{n^s}$ since h_1 is a (μ, s) -independent hash-function.

What is the probability that all keys in the cycle-structure of size s correctly map into their T_2 -cell?

This probability is at most $\frac{\mu}{n^s}$ since h_2 is a (μ, s) -independent hash-function.

These events are independent.

Harald Räcke

7.7 Hashing

Cuckoo Hashing

Harald Räcke

The number of cycle-structures of size *s* is at most

 $s^3 \cdot n^{s-1} \cdot m^{s-1}$.

- There are at most s² possibilities where to attach the forward and backward links.
- There are at most s possibilities to choose where to place key x.
- There are m^{s-1} possibilities to choose the keys apart from *x*.

7.7 Hashing

• There are n^{s-1} possibilities to choose the cells.

Cuckoo Hashing

The probability that a given cycle-structure of size *s* is active is at most $\frac{\mu^2}{n^{2s}}$.

What is the probability that there exists an active cycle structure of size *s*?

Harald Räcke

6. Feb. 2022

6. Feb. 2022

204/308

202/308

7.7 Hashing

6. Feb. 2022 203/308

Cuckoo Hashing The probability that there exists an active cycle-structure is therefore at most $\sum_{s=3}^{\infty} s^3 \cdot n^{s-1} \cdot m^{s-1} \cdot \frac{\mu^2}{n^{2s}} = \frac{\mu^2}{nm} \sum_{s=3}^{\infty} s^3 \left(\frac{m}{n}\right)^s$ $\leq \frac{\mu^2}{m^2} \sum_{s=3}^{\infty} s^3 \left(\frac{1}{1+\epsilon}\right)^s \leq \mathcal{O}\left(\frac{1}{m^2}\right) .$ Here we used the fact that $(1+\epsilon)m \leq n$. Hence, $\Pr[cycle] = \mathcal{O}\left(\frac{1}{m^2}\right) .$

7.7 Hashing

Now, we analyze the probability that a phase is not successful without running into a closed cycle.

Harald Räcke	7.7 Hashing	6. Feb. 2022 206/308

Cuckoo Hashing

Consider the sequence of not necessarily distinct keys starting with x in the order that they are visited during the phase.

Lemma 19

If the sequence is of length p then there exists a sub-sequence of at least $\frac{p+2}{3}$ keys starting with x of distinct keys.

Cuckoo Hashing	
x_{7} x_{9} x_{8} x_{1} x_{2} x_{3} x_{4} x_{5} x_{6} x_{7} x_{1} x_{2} x_{3} x_{4} x_{5} x_{6} x_{7} x_{3} x_{2} x_{1} x_{8} x_{9} x_{1}	p 9
7.7 Hashing Harald Räcke	6. Feb. 2022 207/308

Cuckoo Hashing

Taking $x_1 \rightarrow \cdots \rightarrow x_i$ twice, and $x_1 \rightarrow x_{i+1} \rightarrow \dots x_j$ once gives $2i + (j - i + 1) = i + j + 1 \ge p + 2$ keys. Hence, one of the sequences contains at least (p + 2)/3 keys.

Proof.

Let i be the number of keys (including x) that we see before the first repeated key. Let j denote the total number of distinct keys.

The sequence is of the form:

 $x = x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i \rightarrow x_r \rightarrow x_{r-1} \rightarrow \cdots \rightarrow x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$

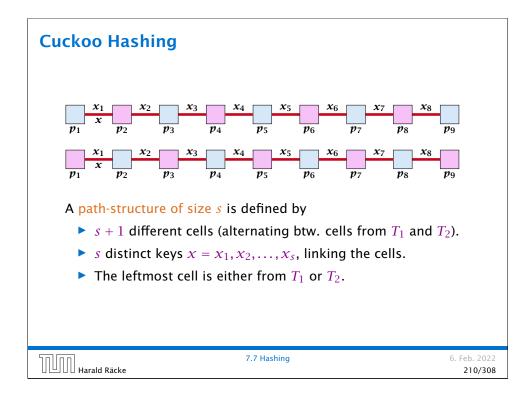

As $r \leq i - 1$ the length *p* of the sequence is

 $p = i + r + (j - i) \le i + j - 1$.

Either sub-sequence $x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i$ or sub-sequence $x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$ has at least $\frac{p+2}{3}$ elements.

7.7 Hashing

6. Feb. 2022 208/308

The probability that a given path-structure of size *s* is active is at most $\frac{\mu^2}{n^{2s}}$.

The probability that there exists an active path-structure of size $\ensuremath{\mathcal{S}}$ is at most

$$\cdot n^{s+1} \cdot m^{s-1} \cdot \frac{\mu^2}{n^{2s}}$$

$$\leq 2\mu^2 \left(\frac{m}{n}\right)^{s-1} \leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{s-1}$$

Plugging in
$$s = (2t + 2)/3$$
 gives

$$\leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t+2)/3-1} = 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t-1)/3} \ .$$

2

7.7 Hashing

Cuckoo Hashing

A path-structure is active if for every key x_{ℓ} (linking a cell p_i from T_1 and a cell p_j from T_2) we have

$$h_1(x_{\ell}) = p_i$$
 and $h_2(x_{\ell}) = p_j$

Observation:

If a phase takes at least t steps without running into a cycle there must exist an active path-structure of size (2t + 2)/3.

```
Note that we count complete steps. A search that touches 2t or 2t + 1 keys takes t steps.
```

7.7 Hashing

Harald Räcke

Cuckoo Hashing

We choose maxsteps $\ge 3\ell/2 + 1/2$. Then the probability that a phase terminates unsuccessfully without running into a cycle is at most

Pr[unsuccessful | no cycle]

 $\leq \Pr[\exists active path-structure of size at least \frac{2maxsteps+2}{3}]$

 $\leq \Pr[\exists active path-structure of size at least \ell + 1]$

 $\leq \Pr[\exists active path-structure of size exactly \ell + 1]$

$$\leq 2\mu^2 \Big(\frac{1}{1+\epsilon}\Big)^\ell \leq \frac{1}{m^2}$$

by choosing $\ell \geq \log\left(\frac{1}{2\mu^2 m^2}\right)/\log\left(\frac{1}{1+\epsilon}\right) = \log\left(2\mu^2 m^2\right)/\log\left(1+\epsilon\right)$

7.7 Hashing

This gives maxsteps = $\Theta(\log m)$.

Note that the existence of a path structure of	ì
size larger than <i>s</i> implies the existence of a	i
path structure of size exactly s.	-

So far we estimated

$$\Pr[\mathsf{cycle}] \le \mathcal{O}\Big(\frac{1}{m^2}\Big)$$

and

 $\Pr[\mathsf{unsuccessful} \mid \mathsf{no cycle}] \le \mathcal{O}\left(\frac{1}{m^2}\right)$

Observe that

Pr[successful] = Pr[no cycle] - Pr[unsuccessful | no cycle] $\geq c \cdot Pr[no cycle]$ Pr[no cycle] C = 0 C = 0 C = 0 C = 0

for a suitable constant c > 0.

Harald Räcke	7.7 Hashing

This means the expected cost for a successful phase is constant (even after accounting for the cost of the incomplete step that finishes the phase).

[Π	Harald	Räcke
]		Harald	Räcke

6. Feb. 2022 216/308

statement but still sufficient for our asymptotic analysis.

6. Feb. 2022 214/308

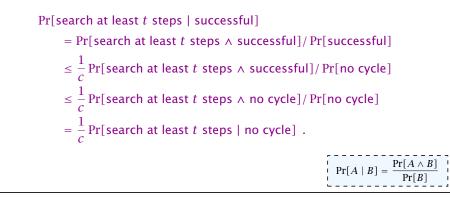

Cuckoo Hashing

The expected number of complete steps in the successful phase of an insert operation is:

E[number of steps | phase successful]

 $= \sum_{t \ge 1} \Pr[\text{search takes at least } t \text{ steps } | \text{ phase successful}]$

We have

Cuckoo Hashing

A phase that is not successful induces cost for doing a complete rehash (this dominates the cost for the steps in the phase).

The probability that a phase is not successful is $q = O(1/m^2)$ (probability $O(1/m^2)$ of running into a cycle and probability $O(1/m^2)$ of reaching maxsteps without running into a cycle).

A rehash try requires m insertions and takes expected constant time per insertion. It fails with probability p := O(1/m).

The expected number of unsuccessful rehashes is $\sum_{i\geq 1} p^i = \frac{1}{1-p} - 1 = \frac{p}{1-p} = \mathcal{O}(p).$

Therefore the expected cost for re-hashes is $\mathcal{O}(m) \cdot \mathcal{O}(p) = \mathcal{O}(1)$.

Formal Proof

Let Y_i denote the event that the *i*-th rehash occurs and does not lead to a valid configuration (i.e., one of the m + 1 insertions fails):

$\Pr[Y_i|Z_i] \le (m+1) \cdot \mathcal{O}(1/m^2) \le \mathcal{O}(1/m) =: p \ .$

Let Z_i denote the event that the *i*-th rehash occurs: The 0-th (re)hash is the initial configuration when doing the pr[Z_i] $\leq \Pr[\wedge_{j=0}^{i-1}Y_j] \leq p^i$

Let X_i^s , $s \in \{1, ..., m + 1\}$ denote the cost for inserting the *s*-th element during the *i*-th rehash (assuming *i*-th rehash occurs):

$$\begin{split} \mathbf{E}[X_i^{S}] &= \mathbf{E}[\mathsf{steps} \mid \mathsf{phase \ successful}] \cdot \Pr[\mathsf{phase \ successful}] \\ &+ \max \mathsf{steps} \cdot \Pr[\mathsf{not \ successful}] = \mathcal{O}(1) \enspace . \end{split}$$

Cuckoo Hashing

What kind of hash-functions do we need?

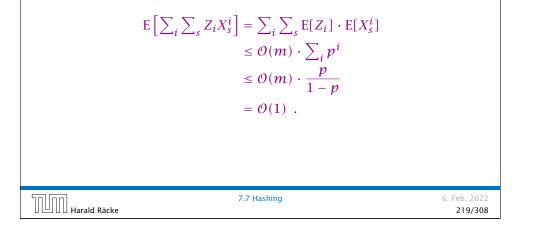

Since maxsteps is $\Theta(\log m)$ the largest size of a path-structure or cycle-structure contains just $\Theta(\log m)$ different keys.

Therefore, it is sufficient to have $(\mu, \Theta(\log m))$ -independent hash-functions.

The expected cost for all rehashes is

 $\mathbf{E}\left[\sum_{i}\sum_{s}Z_{i}X_{i}^{s}\right]$

Note that Z_i is independent of X_j^s , $j \ge i$ (however, it is not independent of X_j^s , j < i). Hence,

Cuckoo Hashing

How do we make sure that $n \ge (1 + \epsilon)m$?

- Let $\alpha := 1/(1 + \epsilon)$.
- Keep track of the number of elements in the table. When $m \ge \alpha n$ we double n and do a complete re-hash (table-expand).
- Whenever *m* drops below $\alpha n/4$ we divide *n* by 2 and do a rehash (table-shrink).
- Note that right after a change in table-size we have $m = \alpha n/2$. In order for a table-expand to occur at least $\alpha n/2$ insertions are required. Similar, for a table-shrink at least $\alpha n/4$ deletions must occur.
- Therefore we can amortize the rehash cost after a change in table-size against the cost for insertions and deletions.

7.7 Hashing

6. Feb. 2022 220/308

Lemma 20

Cuckoo Hashing has an expected constant insert-time and a worst-case constant search-time.

Note that the above lemma only holds if the fill-factor (number of keys/total number of hash-table slots) is at most $\frac{1}{2(1+\epsilon)}$.

The $1/(2(1 + \epsilon))$ fill-factor comes from the fact that the total hash-table is of size 2n (because we have two tables of size n); moreover $m \leq n$ $(1+\epsilon)n$.

8.1 Binary Heaps

- Nearly complete binary tree; only the last level is not full, and this one is filled from left to right.
- Heap property: A node's key is not larger than the key of one of its children.

8.1 Binary Heaps Maintain a pointer to the last element *x*. We can compute the predecessor of x (last element when x is deleted) in time $O(\log n)$. go up until the last edge used was a right edge. go left; go right until you reach a leaf if you hit the root on the way up, go to the rightmost element (19) Harald Räcke 6. Feb. 2022 8.1 Binary Heaps 232/308

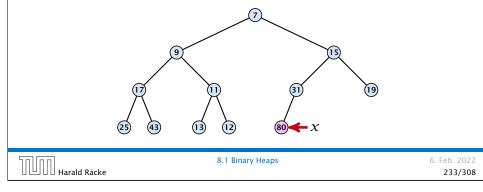

8.1 Binary Heaps

Maintain a pointer to the last element *x*.

We can compute the successor of x
 (last element when an element is inserted) in time O(log n).

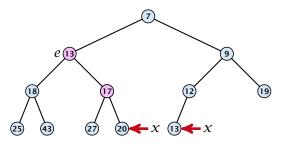

go up until the last edge used was a left edge. go right; go left until you reach a null-pointer.

if you hit the root on the way up, go to the leftmost element; insert a new element as a left child;

Delete

- **1.** Exchange the element to be deleted with the element *e* pointed to by *x*.
- **2.** Restore the heap-property for the element *e*.

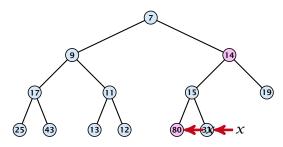

At its new position e may either travel up or down in the tree (but not both directions).

Harald Räcke

6. Feb. 2022 235/308

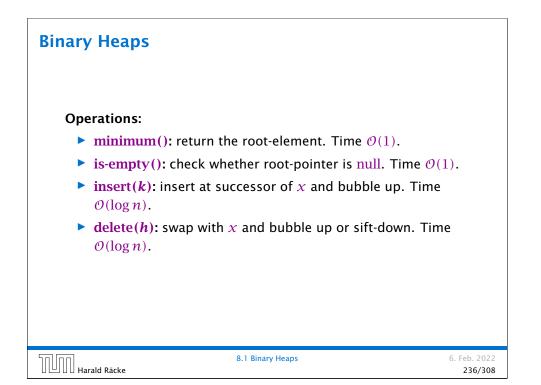

Insert

- **1.** Insert element at successor of *x*.
- 2. Exchange with parent until heap property is fulfilled.

Note that an exchange can either be done by moving the data or by changing pointers. The latter method leads to an addressable priority queue.

Build Heap We can build a heap in linear time: (28) (23) (22) (12) (27) (21) (20) (26) (19)(8)(25)(18)(29) (35) $\sum_{\text{levels } \ell} 2^{\ell} \cdot (h - \ell) = \sum_{i} i 2^{h - i} = \mathcal{O}(2^h) = \mathcal{O}(n)$ 8.1 Binary Heaps 6. Feb. 2022 Harald Räcke

Binary Heaps

The standard implementation of binary heaps is via arrays. Let $A[0,\ldots,n-1]$ be an array

- The parent of *i*-th element is at position $\lfloor \frac{i-1}{2} \rfloor$.
- The left child of *i*-th element is at position 2i + 1.
- The right child of *i*-th element is at position 2i + 2.

Finding the successor of x is much easier than in the description on the previous slide. Simply increase or decrease x.

The resulting binary heap is not addressable. The elements don't maintain their positions and therefore there are no stable handles.

Binary Heaps

Operations:

- **minimum()**: Return the root-element. Time $\mathcal{O}(1)$.
- **is-empty():** Check whether root-pointer is null. Time $\mathcal{O}(1)$.
- insert(k): Insert at x and bubble up. Time $O(\log n)$.
- delete(h): Swap with x and bubble up or sift-down. Time $\mathcal{O}(\log n)$.
- **build** (x_1, \ldots, x_n) : Insert elements arbitrarily; then do sift-down operations starting with the lowest layer in the tree. Time $\mathcal{O}(n)$.

Binomial Trees

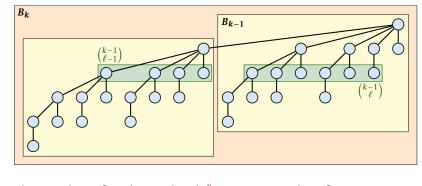

Binomial Trees

The number of nodes on level ℓ in tree B_k is therefore

 $\binom{k-1}{\ell-1} + \binom{k-1}{\ell} = \binom{k}{\ell}$

Sп	1 [חר]	
	ЦI		Harald	Räcke

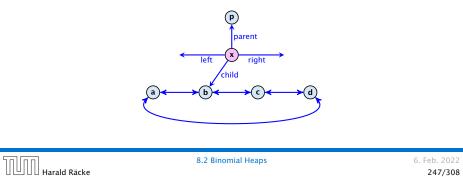

8.2 Binomial Heaps

6. Feb. 2022 245/308

8.2 Binomial Heaps

How do we implement trees with non-constant degree?

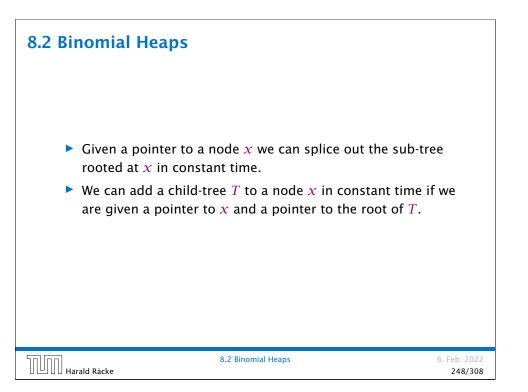

- The children of a node are arranged in a circular linked list.
- A child-pointer points to an arbitrary node within the list.
- A parent-pointer points to the parent node.
- Pointers x.left and x.right point to the left and right sibling of x (if x does not have siblings then x.left = x.right = x).

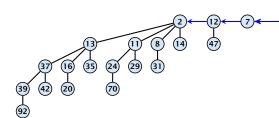

The parent of a node with label b_k, \ldots, b_1 is obtained by setting the least significant 1-bit to 0.

The $\ell\text{-th}$ level contains nodes that have ℓ 1's in their label.

החוחר	8.2 Binomial Heaps	6. Feb. 2022
Harald Räcke		246/308

Binomial Heap

In a binomial heap the keys are arranged in a collection of binomial trees.

Every tree fulfills the heap-property

There is at most one tree for every dimension/order. For example the above heap contains trees B_0 , B_1 , and B_4 .

		-
501		
	11111	
111.		Harald Räcke

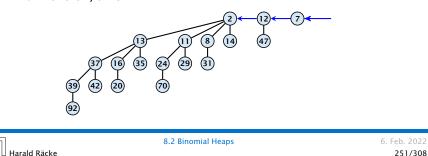

8.2 Binomial Heaps

6. Feb. 2022 249/308

Binomial Heap

Properties of a heap with *n* keys:

- Let $n = b_d b_{d-1}, \ldots, b_0$ denote binary representation of n.
- The heap contains tree B_i iff $b_i = 1$.
- Hence, at most $\lfloor \log n \rfloor + 1$ trees.
- The minimum must be contained in one of the roots.
- The height of the largest tree is at most $\lfloor \log n \rfloor$.
- The trees are stored in a single-linked list; ordered by dimension/size.

Binomial Heap: Merge

Given the number n of keys to be stored in a binomial heap we can deduce the binomial trees that will be contained in the collection.

Let B_{k_1} , B_{k_2} , B_{k_3} , $k_i < k_{i+1}$ denote the binomial trees in the collection and recall that every tree may be contained at most once.

Then $n = \sum_{i} 2^{k_i}$ must hold. But since the k_i are all distinct this means that the k_i define the non-zero bit-positions in the binary representation of n.

Harald Räcke

8.2 Binomial Heaps

6. Feb. 2022 250/308

Binomial Heap: Merge

The merge-operation is instrumental for binomial heaps.

A merge is easy if we have two heaps with different binomial trees. We can simply merge the tree-lists. Note that we do not just do a concatenation as we want to keep the trees in the list sorted according to size.

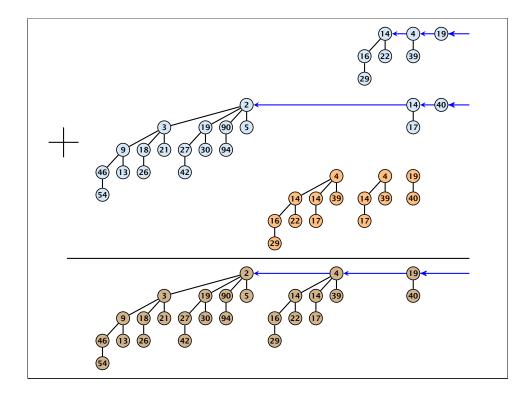

Otherwise, we cannot do this because the merged heap is not allowed to contain two trees of the same order.

Merging two trees of the same size: Add the tree with larger root-value as a child to the other tree.

For more trees the technique is analogous to binary addition.

8.2 Binomial Heaps

All other operations can be reduced to merge().

S. insert(x):

Harald Räcke

• Create a new heap S' that contains just the element x.

8.2 Binomial Heaps

- **Execute** S.merge(S').
- ▶ Time: $O(\log n)$.

8.2 Binomial Heaps

 S_1 . merge(S_2):

- Analogous to binary addition.
- Time is proportional to the number of trees in both heaps.
- ▶ Time: $O(\log n)$.

8.2 Binomial Heaps	6. Feb. 2022 254/308
	8.2 Binomial Heaps

8.2 Binomial Heaps S. minimum():

- Find the minimum key-value among all roots.
- Time: $\mathcal{O}(\log n)$.

6. Feb. 2022

255/308

8.2 Binomial Heaps

S. delete-min():

- Find the minimum key-value among all roots.
- Remove the corresponding tree T_{\min} from the heap.
- Create a new heap S' that contains the trees obtained from T_{\min} after deleting the root (note that these are just $O(\log n)$ trees).
- Compute S.merge(S').
- Time: $\mathcal{O}(\log n)$.

Harald Räcke	8.2 Binomial Heaps	6. Feb. 2022 257/308

8.2 Binomial Heaps

S. delete(handle h):

- **Execute** *S*. decrease-key($h, -\infty$).
- **Execute** *S*. delete-min().
- Time: $\mathcal{O}(\log n)$.

8.2 Binomial Heaps

- *S*. decrease-key(handle *h*):
 - Decrease the key of the element pointed to by *h*.
 - Bubble the element up in the tree until the heap property is fulfilled.
 - Time: $\mathcal{O}(\log n)$ since the trees have height $\mathcal{O}(\log n)$.

Additional implementation details:

- Every node x stores its degree in a field x. degree. Note that this can be updated in constant time when adding a child to x.
- Every node stores a boolean value x.marked that specifies whether x is marked or not.

החוחר	8.3 Fibonacci Heaps	6. Feb. 2022
Harald Räcke		261/308

8.3 Fibonacci Heaps

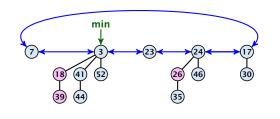

We assume that one unit of potential can pay for a constant amount of work, where the constant is chosen "big enough" (to take care of the constants that occur).

To make this more explicit we use *c* to denote the amount of work that a unit of potential can pay for.

8.3 Fibonacci Heaps

The potential function:

- t(S) denotes the number of trees in the heap.
- m(S) denotes the number of marked nodes.
- We use the potential function $\Phi(S) = t(S) + 2m(S)$.

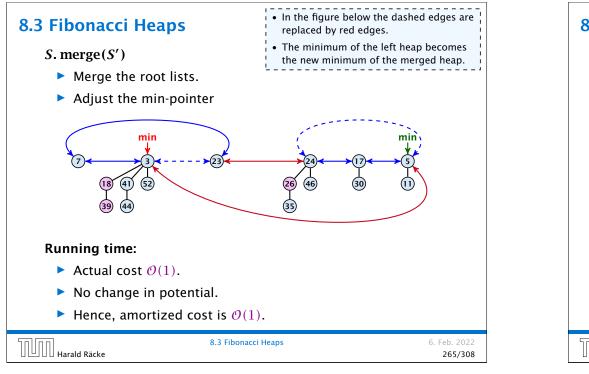

The potential is $\Phi(S) = 5 + 2 \cdot 3 = 11$.

6. Feb. 2022 263/308

 $D(\min)$ is the number of children of the node that stores the minimum.

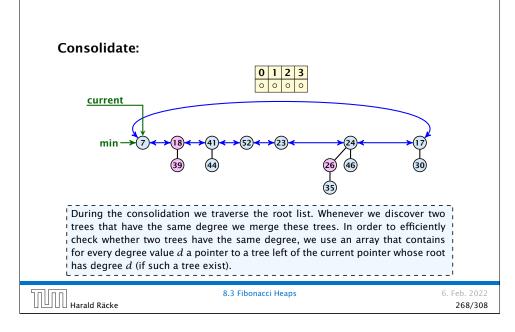

S. delete-min(x)

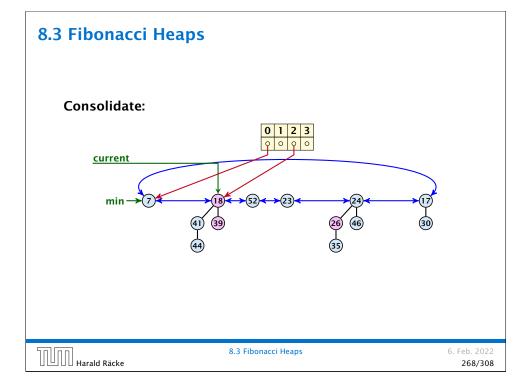

- ► Delete minimum; add child-trees to heap; time: D(min) · O(1).
- Update min-pointer; time: $(t + D(\min)) \cdot O(1)$.

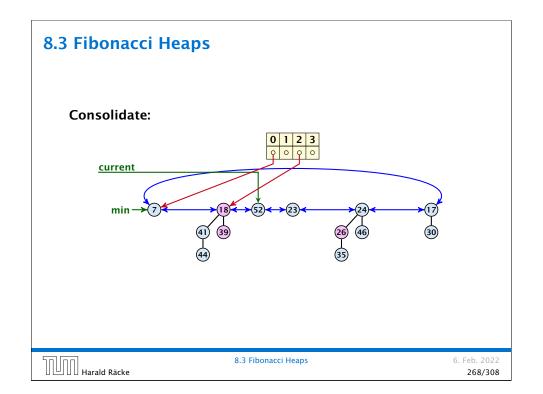

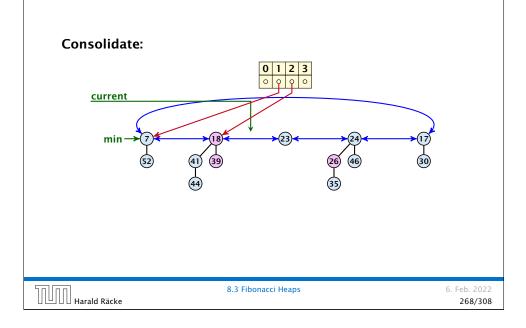

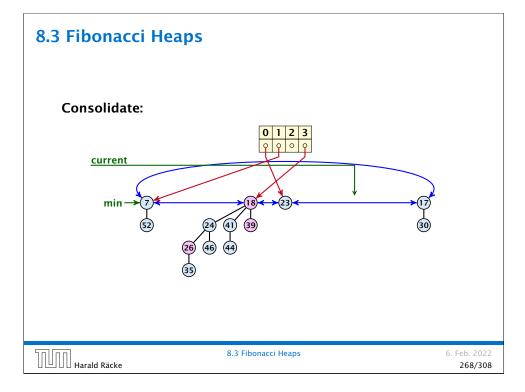

8.3 Fibonacci Heaps

Consolidate: $\begin{array}{c} & 0 & 1 & 2 & 3 \\ \hline & 0 & 0 & 0 & 0 \\ \hline & 0 & 0$

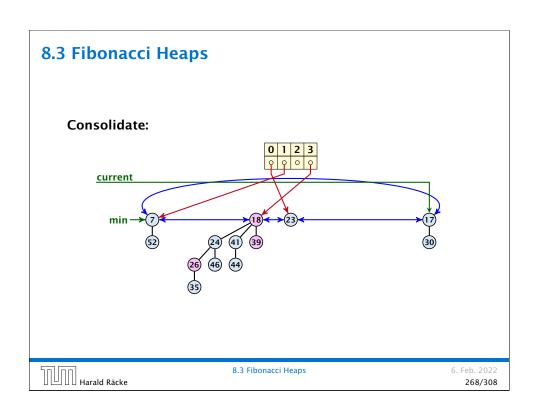

8.3 Fibonacci Heaps Consolidate:

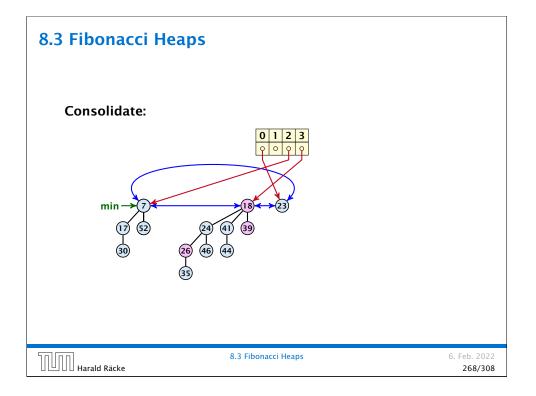

8.3 Fibonacci Heaps

Harald Räcke

6. Feb. 2022

268/308

If the input trees of the consolidation procedure are binomial trees (for example only singleton vertices) then the output will be a set of distinct binomial trees, and, hence, the Fibonacci heap will be (more or less) a Binomial heap right after the consolidation.

If we do not have delete or decrease-key operations then $D_n \leq \log n$.

8.3 Fibonacci Heaps

t and t' denote the number of trees before and after the delete-min() operation, respectively. D_n is an upper bound on the degree (i.e., number of children) of a tree node.

Actual cost for delete-min()

- At most $D_n + t$ elements in root-list before consolidate.
- Actual cost for a delete-min is at most $\mathcal{O}(1) \cdot (D_n + t)$. Hence, there exists c_1 s.t. actual cost is at most $c_1 \cdot (D_n + t)$.

Amortized cost for delete-min()

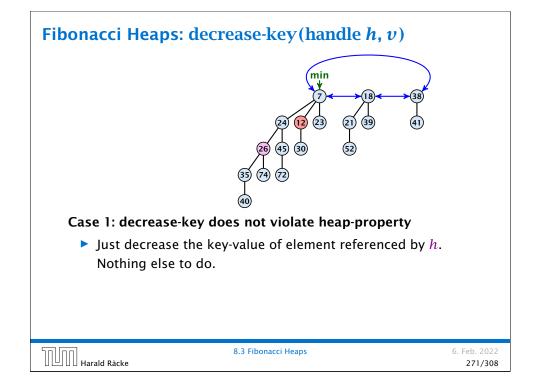

- ▶ $t' \leq D_n + 1$ as degrees are different after consolidating.
- Therefore $\Delta \Phi \leq D_n + 1 t$;
- We can pay $\mathbf{c} \cdot (\mathbf{t} \mathbf{D}_n 1)$ from the potential decrease.
- The amortized cost is

 $c_1 \cdot (D_n + t) - c \cdot (t - D_n - 1)$

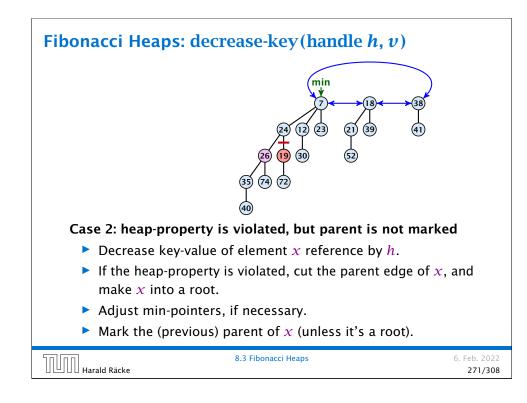

$$\leq (c_1 + c)D_n + (c_1 - c)t + c \leq 2c(D_n + 1) \leq \mathcal{O}(D_n)$$

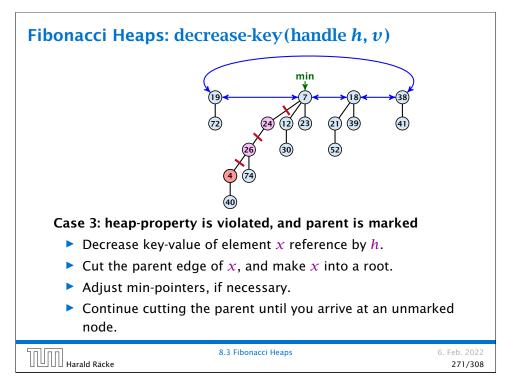

for $c \ge c_1$.

Harald Räcke		269/308

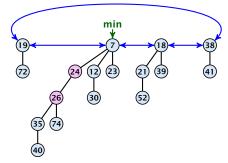

6. Feb. 2022 270/308

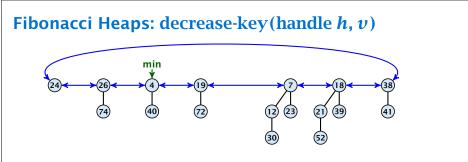

Fibonacci Heaps: decrease-key(handle h, v)

Case 2: heap-property is violated, but parent is not marked

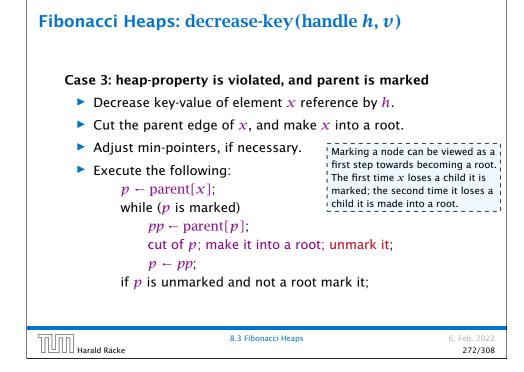

- Decrease key-value of element x reference by h.
- If the heap-property is violated, cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Mark the (previous) parent of x (unless it's a root).

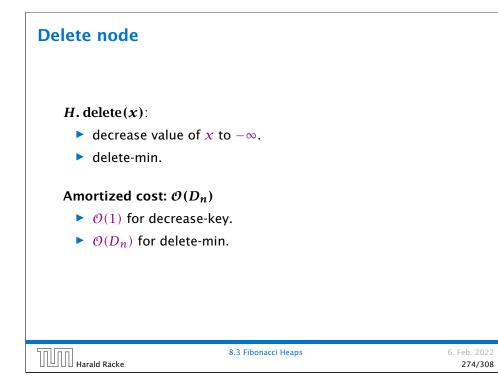

Harald Räcke	8.3 Fibonacci Heaps	6. Feb. 2022
UUU Harald Räcke		271/308

Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element x reference by h.
- Cut the parent edge of *x*, and make *x* into a root.
- Adjust min-pointers, if necessary.
- Continue cutting the parent until you arrive at an unmarked node.

Fibonacci Heaps: decrease-key(handle *h*, *v*)

Actual cost:

- Constant cost for decreasing the value.
- Constant cost for each of ℓ cuts.
- Hence, cost is at most $c_2 \cdot (\ell + 1)$, for some constant c_2 .

Amortized cost:

- $t' = t + \ell$, as every cut creates one new root.
- $m' \le m (\ell 1) + 1 = m \ell + 2$, since all but the first cut unmarks a node; the last cut may mark a node.
- ► $\Delta \Phi \leq \ell + 2(-\ell + 2) = 4 \ell$ ► Amortized cost is at most $c_2(\ell+1) + c(4-\ell) \leq (c_2-c)\ell + 4c + c_2 = O(1)$, m and m': number of marked nodes before and after operation.if $c \geq c_2$. Base Stibonacci Heaps 6. Feb. 2022 273/308

8.3 Fibonad	cci Heaps	
	node with degree k and let $y_1,, y_k$ denote th fx in the order that they were linked to x. Then $degree(y_i) \ge \begin{cases} 0 & \text{if } i = 1\\ i - 2 & \text{if } i > 1 \end{cases}$	
	The marking process is very important for the proof of this lemma. It ensures that a node can have lost at most one child since the last time it became a non-root node. When losing a first child the node gets marked; when losing the second child it is cut from the parent and made into a root.	
Harald Räcke	8.3 Fibonacci Heaps	6. Feb. 2022 275/308

Proof

- When y_i was linked to x, at least y₁,..., y_{i-1} were already linked to x.
- ► Hence, at this time degree(x) ≥ i − 1, and therefore also degree(y_i) ≥ i − 1 as the algorithm links nodes of equal degree only.
- Since, then y_i has lost at most one child.
- Therefore, degree(y_i) $\ge i 2$.

Harald Räcke	8.3 Fibonacci Heaps	6. Feb. 2022 276/308
	8.3 Fibonacci Heaps	

8.3 Fibonacci Heaps

$$\phi = \frac{1}{2}(1 + \sqrt{5})$$
 denotes the *golden ratio*.
Note that $\phi^2 = 1 + \phi$.

6. Feb. 2022 278/308

Definition 22

Consider the following non-standard Fibonacci type sequence:

$$F_k = \begin{cases} 1 & \text{if } k = 0\\ 2 & \text{if } k = 1\\ F_{k-1} + F_{k-2} & \text{if } k \ge 2 \end{cases}$$

Facts:

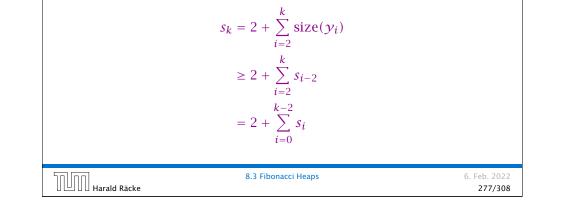

1. $F_k \ge \phi^k$. 2. For $k \ge 2$: $F_k = 2 + \sum_{i=0}^{k-2} F_i$.

The above facts can be easily proved by induction. From this it follows that $s_k \ge F_k \ge \phi^k$, which gives that the maximum degree in a Fibonacci heap is logarithmic.

8.3 Fibonacci Heaps

- Let s_k be the minimum possible size of a sub-tree rooted at a node of degree k that can occur in a Fibonacci heap.
- s_k monotonically increases with k
- ▶ $s_0 = 1$ and $s_1 = 2$.

Let x be a degree k node of size s_k and let y_1, \ldots, y_k be its children.

$$k=0: \qquad 1 = F_0 \ge \Phi^0 = 1$$

$$k=1: \qquad 2 = F_1 \ge \Phi^1 \approx 1.61$$

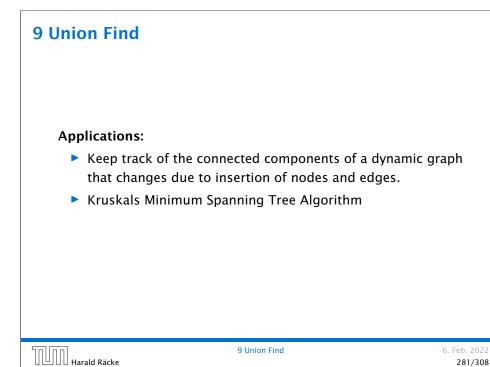

$$k-2, k-1 \rightarrow k: \quad F_k = F_{k-1} + F_{k-2} \ge \Phi^{k-1} + \Phi^{k-2} = \Phi^{k-2}(\Phi+1) = \Phi^k$$

$$k=2: \qquad 3 = F_2 = 2 + 1 = 2 + F_0$$

$$k-1 \rightarrow k: \qquad F_k = F_{k-1} + F_{k-2} = 2 + \sum_{i=0}^{k-3} F_i + F_{k-2} = 2 + \sum_{i=0}^{k-2} F_i$$

The Accounting Method for Amortized Time Bounds

- There is a bank account for every element in the data structure.
- Initially the balance on all accounts is zero.
- Whenever for an operation the amortized time bound exceeds the actual cost, the difference is credited to some bank accounts of elements involved.
- Whenever for an operation the actual cost exceeds the amortized time bound, the difference is charged to bank accounts of some of the elements involved.
- If we can find a charging scheme that guarantees that balances always stay positive the amortized time bounds are proven.

List Implementation

Lemma 23

The list implementation for the ADT union find fulfills the following amortized time bounds:

- ▶ find(x): $\mathcal{O}(1)$.
- makeset(x): $\mathcal{O}(\log n)$.
- union(x, y): $\mathcal{O}(1)$.

Harald Räcke		

6. Feb. 2022 287/308

List Implementation

ากปกก

Harald Räcke

For an operation whose actual cost exceeds the amortized cost we charge the excess to the elements involved.

9 Union Find

- In total we will charge at most O(log n) to an element (regardless of the request sequence).
- For each element a makeset operation occurs as the first operation involving this element.
- We inflate the amortized cost of the makeset-operation to Θ(log n), i.e., at this point we fill the bank account of the element to Θ(log n).
- Later operations charge the account but the balance never drops below zero.

List Implementation

makeset(*x*): The actual cost is $\mathcal{O}(1)$. Due to the cost inflation the amortized cost is $\mathcal{O}(\log n)$.

find(x): For this operation we define the amortized cost and the actual cost to be the same. Hence, this operation does not change any accounts. Cost: O(1).

union(x, y):

- If $S_x = S_y$ the cost is constant; no bank accounts change.
- Otw. the actual cost is $\mathcal{O}(\min\{|S_x|, |S_y|\})$.
- Assume wlog. that S_x is the smaller set; let c denote the hidden constant, i.e., the actual cost is at most $c \cdot |S_x|$.
- Charge *c* to every element in set S_{χ} .

Implementation via Trees Maintain nodes of a set in a tree. The root of the tree is the label of the set. Only pointer to parent exists; we cannot list all elements of a given set. Example: Implementation (1) Implementa

List Implementation

Lemma 24

An element is charged at most $\lfloor \log_2 n \rfloor$ times, where *n* is the total number of elements in the set system.

Proof.

Whenever an element x is charged the number of elements in x's set doubles. This can happen at most $\lfloor \log n \rfloor$ times.

Harald Räcke

6. Feb. 2022 291/308

Implementation via Trees makeset(x) Create a singleton tree. Return pointer to the root. Time: O(1). find(x) Start at element x in the tree. Go upwards until you reach the root. Time: O(level(x)), where level(x) is the distance of element x to the root in its tree. Not constant.

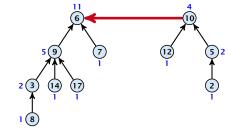

Implementation via Trees

To support union we store the size of a tree in its root.

union(x, y)

- Perform $a \leftarrow \operatorname{find}(x)$; $b \leftarrow \operatorname{find}(y)$. Then: $\operatorname{link}(a, b)$.
- link(a, b) attaches the smaller tree as the child of the larger.
- In addition it updates the size-field of the new root.

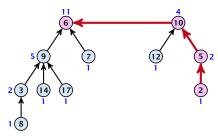

• Time: constant for link(a, b) plus two find-operations.

Path Compression

find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

Note that the size-fields now only give an upper bound on the size of a sub-tree.

Implementation via Trees

Lemma 25

The running time (non-amortized!!!) for find(x) is $O(\log n)$.

Proof.

- When we attach a tree with root c to become a child of a tree with root p, then size(p) ≥ 2 size(c), where size denotes the value of the size-field right after the operation.
- After that the value of size(c) stays fixed, while the value of size(p) may still increase.
- Hence, at any point in time a tree fulfills size(p) ≥ 2 size(c), for any pair of nodes (p, c), where p is a parent of c.

Harald Räcke	9 Union Find	6. Feb. 2022
Harald Räcke		295/308

Path Compression find(x): Go upward until you find the root. Re-attach all visited nodes as children of the root. Speeds up successive find-operations. One could change the algorithm to update the size-fields. This could (2)be done without asymptotically affecting the running time. However, the only size-field that is actually required is the field at the root, which is always correct. We will only use the other sizefields for the proof of Theorem 28. Note that the size-fields now only give an upper bound on the size of a sub-tree. 9 Union Find 6. Feb. 2022 296/308

Path Compression

Asymptotically the cost for a find-operation does not increase due to the path compression heuristic.

However, for a worst-case analysis there is no improvement on the running time. It can still happen that a find-operation takes time $O(\log n)$.

9 Union Find

Amortized Analysis

Lemma 27

There are at most $n/2^s$ nodes of rank s.

Proof.

- Let's say a node v sees node x if v is in x's sub-tree at the time that x becomes a child.
- A node v sees at most one node of rank s during the running time of the algorithm.
- This holds because the rank-sequence of the roots of the different trees that contain v during the running time of the algorithm is a strictly increasing sequence.
- Hence, every node sees at most one rank s node, but every rank s node is seen by at least 2^s different nodes.

6. Feb. 2022 297/308

Amortized Analysis

Definitions:

size(v) = the number of nodes that were in the sub-tree rooted at v when v became the child of another node (or the number of nodes if v is the root).

Note that this is the same as the size of v's subtree in the case that there are no find-operations.

► rank(v) = $\lfloor \log(size(v)) \rfloor$.

 $\blacktriangleright \Rightarrow \operatorname{size}(v) \ge 2^{\operatorname{rank}(v)}.$

Lemma 26

The rank of a parent must be strictly larger than the rank of a child.

החתר	9 Union Find	6. Feb. 2022

• union $(x, y) : \mathcal{O}(\log^*(n))$

Harald Räcke

Amortized Analysis

In the following we assume $n \ge 2$.

rank-group:

- A node with rank rank(v) is in rank group $log^*(rank(v))$.
- The rank-group g = 0 contains only nodes with rank 0 or rank 1.
- A rank group $g \ge 1$ contains ranks tow $(g 1) + 1, \dots, tow(g)$.
- ▶ The maximum non-empty rank group is $\log^*(\lfloor \log n \rfloor) \le \log^*(n) 1$ (which holds for $n \ge 2$).
- Hence, the total number of rank-groups is at most $\log^* n$.

5000	9 Union Find
Harald Bäcke	

Amortized Analysis

Observations:

- ► A find-account is charged at most log*(n) times (once for the root and at most log*(n) - 1 times when increasing the rank-group).
- After a node v is charged its parent-edge is re-assigned. The rank of the parent strictly increases.
- After some charges to v the parent will be in a larger rank-group. ⇒ v will never be charged again.
- The total charge made to a node in rank-group g is at most tow(g) - tow(g − 1) − 1 ≤ tow(g).

Amortized Analysis

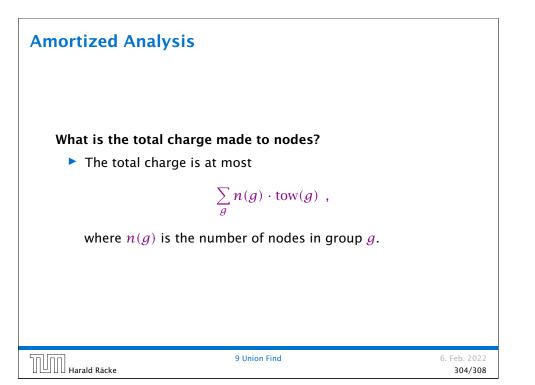

Accounting Scheme:

- create an account for every find-operation
- \blacktriangleright create an account for every node v

The cost for a find-operation is equal to the length of the path traversed. We charge the cost for going from v to parent[v] as follows:

- If parent[v] is the root we charge the cost to the find-account.
- If the group-number of rank(v) is the same as that of rank(parent[v]) (before starting path compression) we charge the cost to the node-account of v.
- Otherwise we charge the cost to the find-account.

החוחר	9 Union Find	6. Feb. 2022
UUU Harald Räcke		302/308

6. Feb. 2022 303/308

6. Feb. 2022 301/308

Amortized Analysis

For $g \ge 1$ we have

$$n(g) \le \sum_{s=\text{tow}(g-1)+1}^{\text{tow}(g)} \frac{n}{2^s} \le \sum_{s=\text{tow}(g-1)+1}^{\infty} \frac{n}{2^s}$$
$$= \frac{n}{2^{\text{tow}(g-1)+1}} \sum_{s=0}^{\infty} \frac{1}{2^s} = \frac{n}{2^{\text{tow}(g-1)+1}} \cdot 2$$
$$= \frac{n}{2^{\text{tow}(g-1)}} = \frac{n}{\text{tow}(g)} .$$

Hence,

$$\sum_{g} n(g) \operatorname{tow}(g) \le n(0) \operatorname{tow}(0) + \sum_{g \ge 1} n(g) \operatorname{tow}(g) \le n \log^*(n)$$

Harald Räcke

9 Union Find

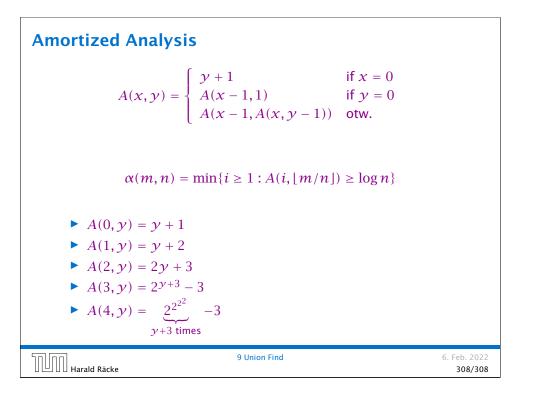

Amortized Analysis The analysis is not tight. In fact it has been shown that the amortized time for the union-find data structure with path compression is $\mathcal{O}(\alpha(m, n))$, where $\alpha(m, n)$ is the inverse Ackermann function which grows a lot lot slower than $\log^* n$. (Here, we consider the average running time of m operations on at most n elements). There is also a lower bound of $\Omega(\alpha(m, n))$.

Amortized Analysis

Without loss of generality we can assume that all makeset-operations occur at the start.

This means if we inflate the cost of makeset to $\log^* n$ and add this to the node account of v then the balances of all node accounts will sum up to a positive value (this is sufficient to obtain an amortized bound).
