## Part III

## **Data Structures**

9. Jan. 2023 15/344

# **Dynamic Set Operations**

- ▶ *S.* search(*k*): Returns pointer to object x from S with key[x] = k or null.
- ► S. insert(x): Inserts object x into set S. key[x] must not currently exist in the data-structure.
- ▶ S. delete(x): Given pointer to object x from S, delete x from the set.
- ► *S.* minimum(): Return pointer to object with smallest key-value in *S*.
- ► *S.* maximum(): Return pointer to object with largest key-value in *S*.
- ► *S.* successor(*x*): Return pointer to the next larger element in *S* or null if *x* is maximum.
- ► *S.* predecessor(*x*): Return pointer to the next smaller element in *S* or null if *x* is minimum.

## **Abstract Data Type**

An abstract data type (ADT) is defined by an interface of operations or methods that can be performed and that have a defined behavior.

The data types in this lecture all operate on objects that are represented by a [key, value] pair.

- ► The key comes from a totally ordered set, and we assume that there is an efficient comparison function.
- ► The value can be anything; it usually carries satellite information important for the application that uses the ADT.

Harald Räcke

9. Jan. 2023

16/344

# **Dynamic Set Operations**

- ▶ *S.* union(S'): Sets  $S := S \cup S'$ . The set S' is destroyed.
- ▶ S. merge(S'): Sets  $S := S \cup S'$ . Requires  $S \cap S' = \emptyset$ .
- ► S. split(k, S'):  $S := \{x \in S \mid \text{key}[x] \le k\}, S' := \{x \in S \mid \text{key}[x] > k\}.$
- ► S. concatenate(S'):  $S := S \cup S'$ . Requires  $\text{key}[S. \text{maximum}()] \le \text{key}[S'. \text{minimum}()]$ .
- ► *S.* decrease-key(x, k): Replace key[x] by  $k \le key[x]$ .

Harald Räcke

9. Jan. 2023 **17/344**  9. Jan. 2023 1**8/344** 

## **Examples of ADTs**

#### Stack:

- $\triangleright$  S. push(x): Insert an element.
- ► *S.* pop(): Return the element from *S* that was inserted most recently; delete it from *S*.
- ▶ *S*. empty(): Tell if *S* contains any object.

#### Queue:

- ► S. enqueue(x): Insert an element.
- ► *S.* dequeue(): Return the element that is longest in the structure; delete it from *S*.
- **S.** empty(): Tell if S contains any object.

#### **Priority-Queue**:

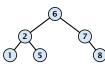

- $\triangleright$  S. insert(x): Insert an element.
- ► *S.* delete-min(): Return the element with lowest key-value; delete it from *S*.

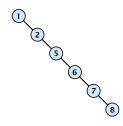

## 7.1 Binary Search Trees

An (internal) binary search tree stores the elements in a binary tree. Each tree-node corresponds to an element. All elements in the left sub-tree of a node v have a smaller key-value than  $\ker[v]$  and elements in the right sub-tree have a larger-key value. We assume that all key-values are different.

(External Search Trees store objects only at leaf-vertices)

## Examples:

## 7 Dictionary

#### Dictionary:

- $\triangleright$  S. insert(x): Insert an element x.
- S. delete(x): Delete the element pointed to by x.
- S. search(k): Return a pointer to an element e with key[e] = k in S if it exists; otherwise return null.

7 Dictionary

9. Jan. 2023

22/344

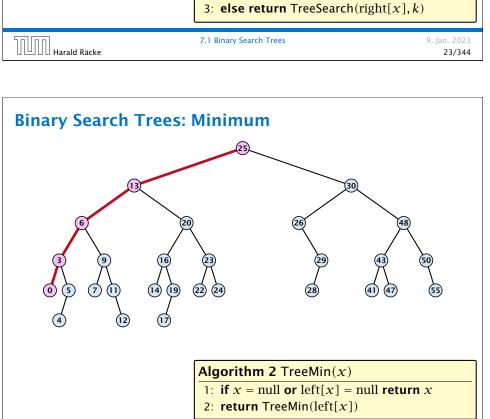

20/344

## 7.1 Binary Search Trees

We consider the following operations on binary search trees. Note that this is a super-set of the dictionary-operations.

- ightharpoonup T. insert(x)
- ightharpoonup T. delete(x)
- ightharpoonup T. search(k)
- $ightharpoonup T. \operatorname{successor}(x)$
- ightharpoonup T. predecessor(x)
- ► T. minimum()
- ► T. maximum()

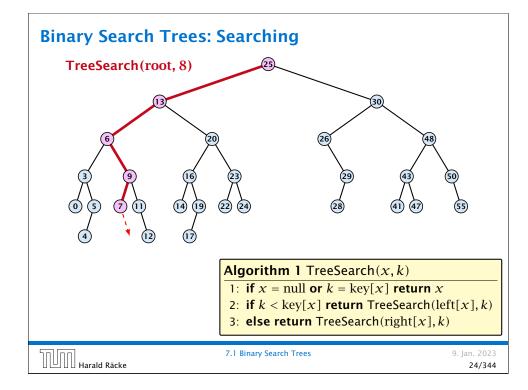

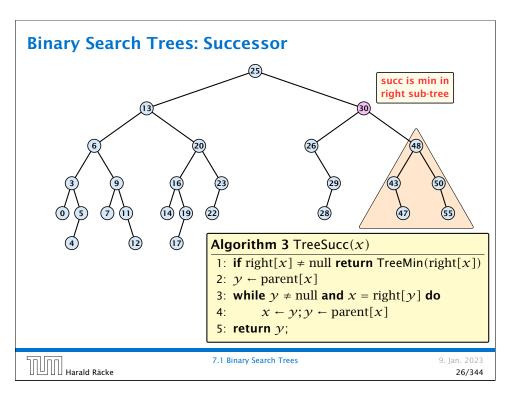

7.1 Binary Search Trees

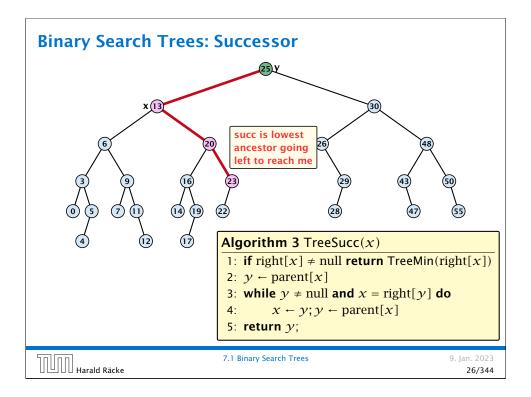

||||||||| Harald Räcke

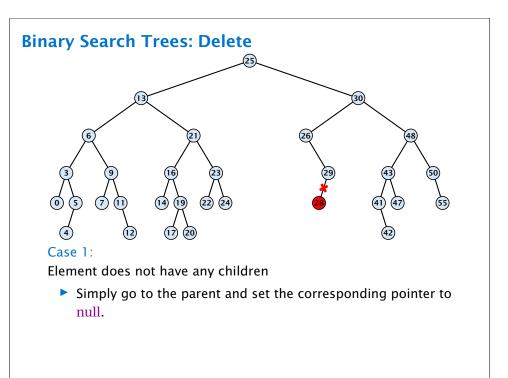

9. Jan. 2023

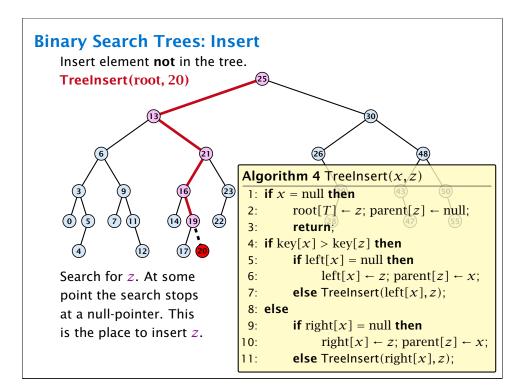

25/344

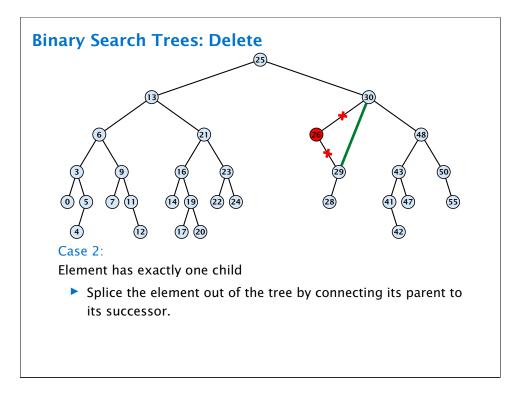

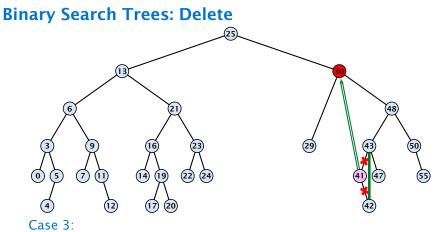

Element has two children

- Find the successor of the element
- Splice successor out of the tree
- ▶ Replace content of element by content of successor

## **Balanced Binary Search Trees**

All operations on a binary search tree can be performed in time O(h), where h denotes the height of the tree.

However the height of the tree may become as large as  $\Theta(n)$ .

## **Balanced Binary Search Trees**

With each insert- and delete-operation perform local adjustments to guarantee a height of  $O(\log n)$ .

AVL-trees, Red-black trees, Scapegoat trees, 2-3 trees, B-trees, AA trees, Treaps

similar: SPLAY trees.

## **Binary Search Trees: Delete**

```
Algorithm 9 TreeDelete(z)
 1: if left[z] = null or right[z] = null
          then y \leftarrow z else y \leftarrow \text{TreeSucc}(z);
                                                            select y to splice out
 3: if left[\gamma] \neq null
          then x \leftarrow \text{left}[y] else x \leftarrow \text{right}[y]; x is child of y (or null)
 5: if x \neq \text{null then parent}[x] \leftarrow \text{parent}[y];
                                                             parent[x] is correct
 6: if parent[\gamma] = null then
 7:
          root[T] \leftarrow x
 8: else
          if y = left[parent[y]] then
                                                                   fix pointer to x
 9:
10:
                 left[parent[\gamma]] \leftarrow x
          else
11:
                 right[parent[v]] \leftarrow x
12:
13: if y \neq z then copy y-data to z
```

9. Jan. 2023 31/344

#### 7.2 Red Black Trees

#### **Definition 1**

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- 3. For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data

7.2 Red Black Trees

9. Jan. 2023

31/344

#### 7.2 Red Black Trees

#### Lemma 2

A red-black tree with n internal nodes has height at most  $O(\log n)$ .

#### **Definition 3**

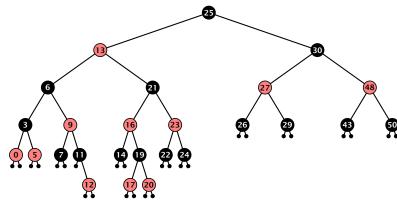

The black height  $\mathrm{bh}(v)$  of a node v in a red black tree is the number of black nodes on a path from v to a leaf vertex (not counting v).

We first show:

#### Lemma 4

A sub-tree of black height bh(v) in a red black tree contains at least  $2^{bh(v)}-1$  internal vertices.

Harald Räcke

7.2 Red Black Trees

9. Jan. 2023

32/344

#### 7.2 Red Black Trees

#### **Proof of Lemma 4.**

Induction on the height of v.

**base case** (height(v) = 0)

- ▶ If height(v) (maximum distance btw. v and a node in the sub-tree rooted at v) is 0 then v is a leaf.
- ightharpoonup The black height of v is 0.
- ► The sub-tree rooted at v contains  $0 = 2^{\text{bh}(v)} 1$  inner vertices.

#### 7.2 Red Black Trees

#### **Proof (cont.)**

#### induction step

- ▶ Supose v is a node with height(v) > 0.
- v has two children with strictly smaller height.
- ▶ These children  $(c_1, c_2)$  either have  $bh(c_i) = bh(v)$  or  $bh(c_i) = bh(v) - 1.$
- ▶ By induction hypothesis both sub-trees contain at least  $2^{bh(v)-1}-1$  internal vertices.
- ▶ Then  $T_v$  contains at least  $2(2^{bh(v)-1}-1)+1 \ge 2^{bh(v)}-1$ vertices.

7.2 Red Black Trees

9. lan. 2023 35/344

#### 7.2 Red Black Trees

#### **Definition 1**

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- 3. For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers

#### 7.2 Red Black Trees

#### Proof of Lemma 2.

Let h denote the height of the red-black tree, and let P denote a path from the root to the furthest leaf.

At least half of the node on P must be black, since a red node must be followed by a black node.

Hence, the black height of the root is at least h/2.

The tree contains at least  $2^{h/2} - 1$  internal vertices. Hence,  $2^{h/2} - 1 < n$ .

Hence, 
$$h \le 2\log(n+1) = \mathcal{O}(\log n)$$
.

Harald Räcke

7.2 Red Black Trees

9. Jan. 2023 36/344

Harald Räcke

to special null-vertices, that do not carry any object-data.

7.2 Red Black Trees

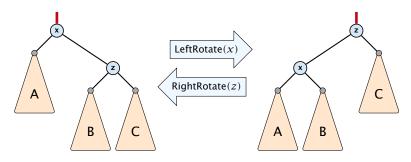

We need to adapt the insert and delete operations so that the red black properties are maintained.

7.2 Red Black Trees 9. lan. 2023 37/344 7.2 Red Black Trees

9. lan. 2023 38/344

#### **Rotations**

The properties will be maintained through rotations:

Harald Räcke

7.2 Red Black Trees

9. Jan. 2023

39/344

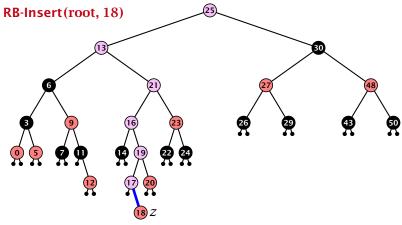

### **Red Black Trees: Insert**

#### Invariant of the fix-up algorithm:

- z is a red node
- ▶ the black-height property is fulfilled at every node
- the only violation of red-black properties occurs at z and parent[z]
  - either both of them are red (most important case)
  - or the parent does not exist (violation since root must be black)

If z has a parent but no grand-parent we could simply color the parent/root black; however this case never happens.

#### **Red Black Trees: Insert**

#### Insert:

- first make a normal insert into a binary search tree
- then fix red-black properties

Harald Räcke

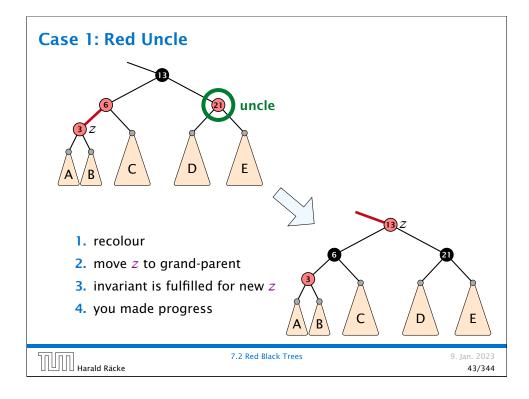

7.2 Red Black Trees

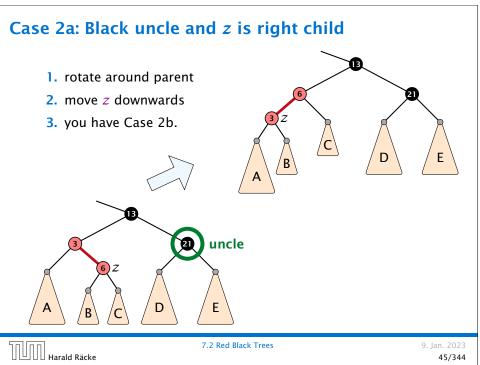

9. Jan. 2023

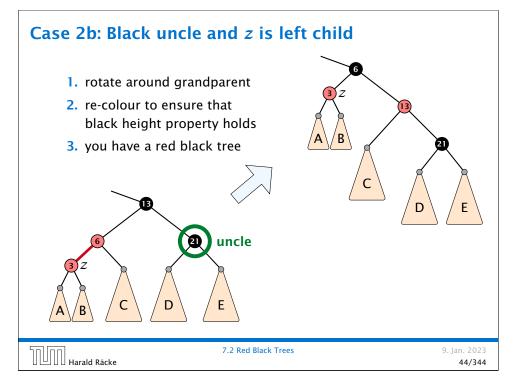

40/344

### **Red Black Trees: Insert**

```
Algorithm 10 InsertFix(z)
1: while parent[z] \neq null and col[parent[z]] = red do
        if parent[z] = left[gp[z]] then z in left subtree of grandparent
             uncle \leftarrow right[grandparent[z]]
3:
             if col[uncle] = red then
4:
                                                            Case 1: uncle red
                  col[p[z]] \leftarrow black; col[u] \leftarrow black;
5:
                  col[gp[z]] \leftarrow red; z \leftarrow grandparent[z];
6:
7:
             else
                                                          Case 2: uncle black
                  if z = right[parent[z]] then
 8:
                                                             2a: z right child
                      z \leftarrow p[z]; LeftRotate(z);
9:
                  col[p[z]] \leftarrow black; col[gp[z]] \leftarrow red; 2b: z left child
10:
                  RightRotate(gp[z]);
11:
        else same as then-clause but right and left exchanged
13: col(root[T]) \leftarrow black;
```

## **Red Black Trees: Insert**

#### Running time:

- ▶ Only Case 1 may repeat; but only h/2 many steps, where h is the height of the tree.
- ► Case 2a → Case 2b → red-black tree
- ► Case 2b → red-black tree

Performing Case 1 at most  $O(\log n)$  times and every other case at most once, we get a red-black tree. Hence  $\mathcal{O}(\log n)$  re-colorings and at most 2 rotations.

#### **Red Black Trees: Delete**

First do a standard delete.

If the spliced out node x was red everything is fine.

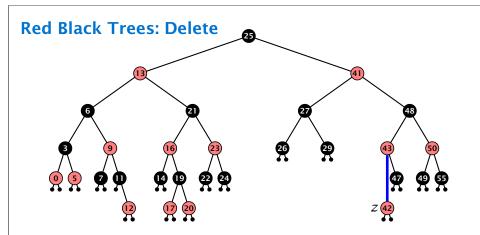

If it was black there may be the following problems.

- $\triangleright$  Parent and child of x were red; two adjacent red vertices.
- If you delete the root, the root may now be red.
- Every path from an ancestor of x to a descendant leaf of x changes the number of black nodes. Black height property might be violated.

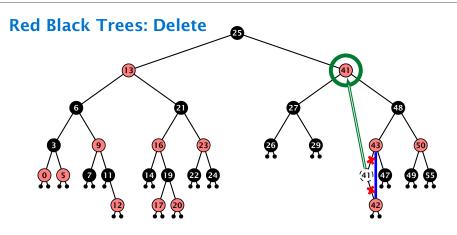

7.2 Red Black Trees

9. Jan. 2023 47/344

#### Delete:

- deleting black node messes up black-height property
- if z is red, we can simply color it black and everything is fine
- ► the problem is if z is black (e.g. a dummy-leaf); we call a fix-up procedure to fix the problem.

#### Case 3:

Element has two children

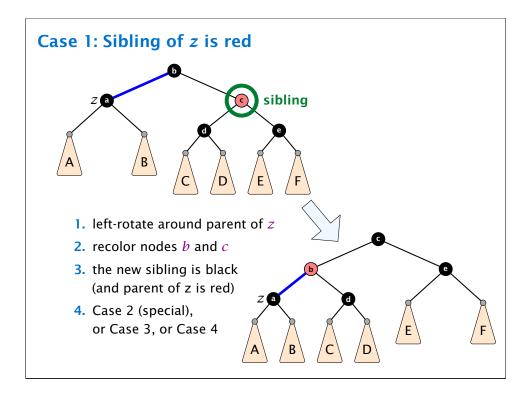

- do normal delete
- when replacing content by content of successor, don't change color of node

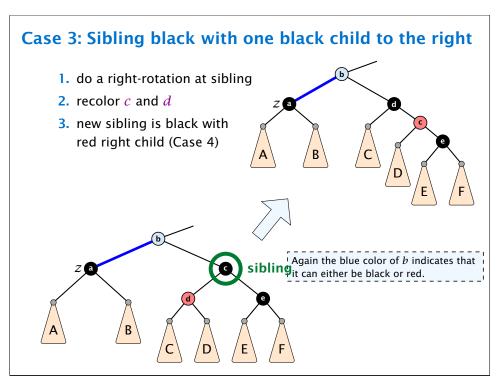

#### **Red Black Trees: Delete**

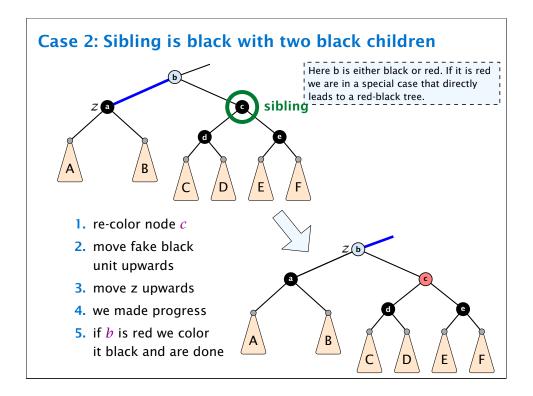

## Invariant of the fix-up algorithm

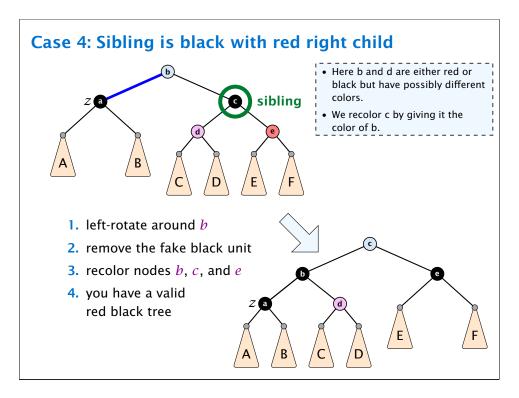

- ► the node *z* is black
- ▶ if we "assign" a fake black unit to the edge from z to its parent then the black-height property is fulfilled

**Goal:** make rotations in such a way that you at some point can remove the fake black unit from the edge.

### Running time:

- only Case 2 can repeat; but only h many steps, where h is the height of the tree
- Case 1 → Case 2 (special) → red black tree
  - Case 1 → Case 3 → Case 4 → red black tree
  - Case 1 → Case 4 → red black tree
- ► Case 3 → Case 4 → red black tree
- Case 4 → red black tree

Performing Case 2 at most  $\mathcal{O}(\log n)$  times and every other step at most once, we get a red black tree. Hence,  $\mathcal{O}(\log n)$  re-colorings and at most 3 rotations.

7.2 Red Black Trees

9. Jan. 2023

55/344

## **Splay Trees**

### Disadvantage of balanced search trees:

- worst case; no advantage for easy inputs
- additional memory required
- complicated implementation

#### **Splay Trees:**

- + after access, an element is moved to the root; splay(x) repeated accesses are faster
- only amortized guarantee
- read-operations change the tree

#### **Red-Black Trees**

#### Bibliography

[CLRS90] Thomas H. Cormen, Charles E. Leiserson, Ron L. Rivest, Clifford Stein: Introduction to Algorithms (3rd ed.), MIT Press and McGraw-Hill, 2009

Red black trees are covered in detail in Chapter 13 of [CLRS90].

Harald Räcke

7.2 Red Black Trees

9. Jan. 2023 56/344

**Splay Trees** 

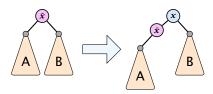

#### find(x)

- search for x according to a search tree
- let  $\bar{x}$  be last element on search-path
- splay( $\bar{x}$ )

## **Splay Trees**

#### insert(x)

- ▶ search for x;  $\bar{x}$  is last visited element during search (successer or predecessor of x)
- splay( $\bar{x}$ ) moves  $\bar{x}$  to the root
- insert x as new root

The illustration shows the case when  $\bar{x}$  is the predecessor of x.

Harald Räcke

7.3 Splay Trees

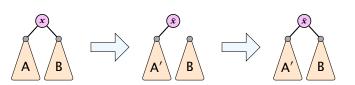

9. Jan. 2023

58/344

## **Splay Trees**

#### delete(x)

- ightharpoonup search for x; splay(x); remove x
- ightharpoonup search largest element  $\bar{x}$  in A
- splay( $\bar{x}$ ) (on subtree A)
- ▶ connect root of B as right child of  $\bar{x}$

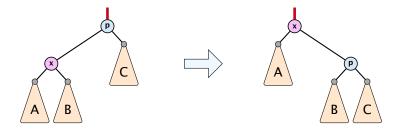

Harald Räcke

7.3 Splay Trees

9. Jan. 2023

59/344

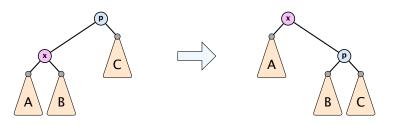

#### **Move to Root**

## How to bring element to root?

- one (bad) option: moveToRoot(x)
- iteratively do rotation around parent of x until x is root
- ▶ if *x* is left child do right rotation otw. left rotation

# **Splay: Zig Case**

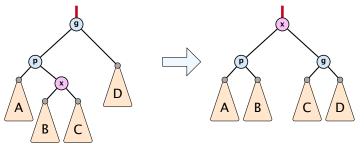

## better option splay(x):

zig case: if x is child of root do left rotation or right rotation around parent

Note that moveToRoot(x) does the same.

# **Splay: Zigzag Case**

#### better option splay(x):

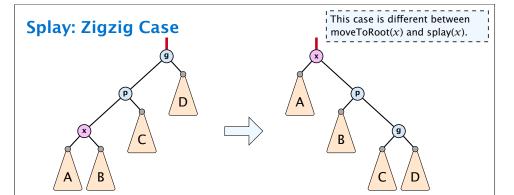

- zigzag case: if x is right child and parent of x is left child (or x left child parent of x right child)
- do double right rotation around grand-parent (resp. double left rotation)

Note that moveToRoot(x) does the same.

Harald Räcke

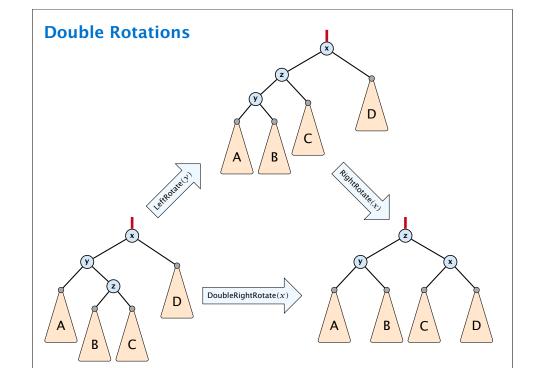

7.3 Splay Trees

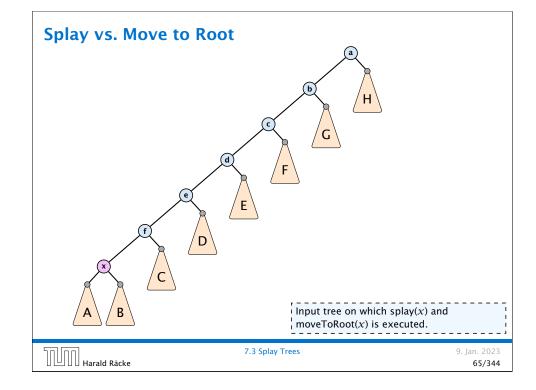

62/344

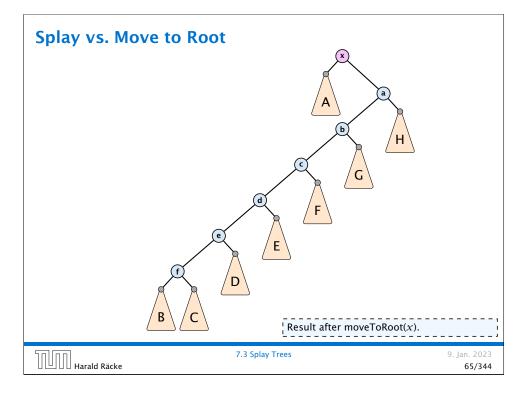

#### better option splay(x):

- zigzig case: if x is left child and parent of x is left child (or x right child, parent of x right child)
- do right roation around grand-parent followed by right rotation around parent (resp. left rotations)

# **Static Optimality**

|||||||| Harald Räcke

Suppose we have a sequence of m find-operations. find(x) appears  $h_x$  times in this sequence.

The cost of a **static** search tree *T* is:

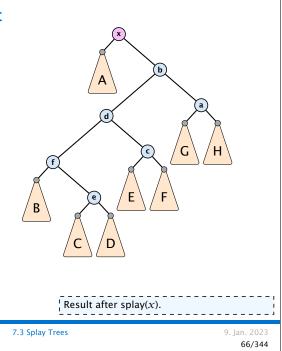

$$cost(T) = m + \sum_{x} h_x \operatorname{depth}_{T}(x)$$

The total cost for processing the sequence on a splay-tree is  $\mathcal{O}(\cos(T_{\min}))$ , where  $T_{\min}$  is an optimal static search tree.

depth<sub>T</sub>(x) is the number of edges on a path from the root of T to x.

Theorem given without proof.

Splay vs. Move to Root

# **Dynamic Optimality**

Harald Räcke

Let S be a sequence with m find-operations.

Let A be a data-structure based on a search tree:

- the cost for accessing element x is 1 + depth(x);
- after accessing x the tree may be re-arranged through rotations;

7.3 Splay Trees

## **Conjecture:**

A splay tree that only contains elements from S has cost  $\mathcal{O}(\cos t(A,S))$ , for processing S.

#### Lemma 5

Splay Trees have an amortized running time of  $O(\log n)$  for all operations.

7.3 Splay Trees

9. lan. 2023

69/344

#### **Potential Method**

Introduce a potential for the data structure.

- $lackbox{}{}\Phi(D_i)$  is the potential after the *i*-th operation.
- $\blacktriangleright$  Amortized cost of the *i*-th operation is

$$\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1}) .$$

▶ Show that  $\Phi(D_i) \ge \Phi(D_0)$ .

Then

$$\sum_{i=1}^{k} c_i \le \sum_{i=1}^{k} c_i + \Phi(D_k) - \Phi(D_0) = \sum_{i=1}^{k} \hat{c}_i$$

This means the amortized costs can be used to derive a bound on the total cost.

## **Amortized Analysis**

#### **Definition 6**

A data structure with operations  $op_1(), \dots, op_k()$  has amortized running times  $t_1, \ldots, t_k$  for these operations if the following holds.

Suppose you are given a sequence of operations (starting with an empty data-structure) that operate on at most n elements, and let  $k_i$  denote the number of occurrences of op<sub>i</sub>() within this sequence. Then the actual running time must be at most  $\sum_i k_i \cdot t_i(n)$ .

7.3 Splay Trees

9. Jan. 2023

70/344

## **Example: Stack**

#### Stack

- ► S. push()
- ► S. pop()
- S. multipop(k): removes k items from the stack. If the stack currently contains less than k items it empties the stack.
- ▶ The user has to ensure that pop and multipop do not generate an underflow.

#### Actual cost:

- ► *S.* push(): cost 1.
- ► S. pop(): cost 1.
- *S.* multipop(k): cost min{size, k} = k.

## **Example: Stack**

Use potential function  $\Phi(S) = \text{number of elements on the stack.}$ 

#### Amortized cost:

**►** *S.* push(): cost

$$\hat{C}_{\text{push}} = C_{\text{push}} + \Delta \Phi = 1 + 1 \le 2 .$$

► *S.* pop(): cost

$$\hat{C}_{\text{pop}} = C_{\text{pop}} + \Delta \Phi = 1 - 1 \le 0 .$$

 $\triangleright$  S. multipop(k): cost

$$\hat{C}_{mp} = C_{mp} + \Delta \Phi = \min\{\text{size}, k\} - \min\{\text{size}, k\} \le 0$$
.

7.3 Splay Trees

9. Jan. 2023

73/344

# **Example: Binary Counter**

Choose potential function  $\Phi(x) = k$ , where k denotes the number of ones in the binary representation of x.

#### Amortized cost:

► Changing bit from 0 to 1:

$$\hat{C}_{0\to 1} = C_{0\to 1} + \Delta \Phi = 1 + 1 \le 2 .$$

► Changing bit from 1 to 0:

$$\hat{C}_{1\to 0} = C_{1\to 0} + \Delta \Phi = 1 - 1 \le 0$$
.

▶ Increment: Let k denotes the number of consecutive ones in the least significant bit-positions. An increment involves k (1  $\rightarrow$  0)-operations, and one (0  $\rightarrow$  1)-operation.

Hence, the amortized cost is  $k\hat{C}_{1\rightarrow 0} + \hat{C}_{0\rightarrow 1} \leq 2$ .

## **Example: Binary Counter**

#### Incrementing a binary counter:

Consider a computational model where each bit-operation costs one time-unit.

Incrementing an n-bit binary counter may require to examine n-bits, and maybe change them.

#### **Actual cost:**

- ► Changing bit from 0 to 1: cost 1.
- ► Changing bit from 1 to 0: cost 1.
- ▶ Increment: cost is k + 1, where k is the number of consecutive ones in the least significant bit-positions (e.g, 001101 has k = 1).

7.3 Splay Trees

9. Jan. 2023

74/344

# **Splay Trees**

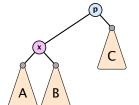

## potential function for splay trees:

- ightharpoonup size  $s(x) = |T_x|$
- ightharpoonup rank  $r(x) = \log_2(s(x))$
- $\blacktriangleright \Phi(T) = \sum_{v \in T} r(v)$

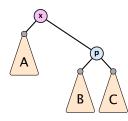

amortized cost = real cost + potential change

The cost is essentially the cost of the splay-operation, which is 1 plus the number of rotations.

## **Splay: Zig Case**

$$\Delta\Phi = r'(x) + r'(p) - r(x) - r(p)$$
$$= r'(p) - r(x)$$
$$\leq r'(x) - r(x)$$

$$cost_{zig} \le 1 + 3(r'(x) - r(x))$$

Harald Räcke

7.3 Splay Trees

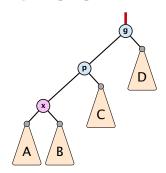

9. Jan. 2023 77/344

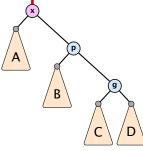

The last inequality holds

because log is a concave

function.

Splay: Zigzig Case

$$\frac{1}{2} \left( r(x) + r'(g) - 2r'(x) \right)$$

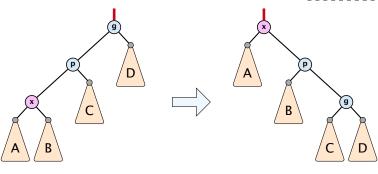

$$= \frac{1}{2} \left( \log(s(x)) + \log(s'(g)) - 2\log(s'(x)) \right)$$

$$= \frac{1}{2} \log \left( \frac{s(x)}{s'(x)} \right) + \frac{1}{2} \log \left( \frac{s'(g)}{s'(x)} \right)$$

$$\leq \log \left( \frac{1}{2} \frac{s(x)}{s'(x)} + \frac{1}{2} \frac{s'(g)}{s'(x)} \right) \leq \log \left( \frac{1}{2} \right) = -1$$

# **Splay: Zigzig Case**

Last inequality follows from next slide.

$$\Delta \Phi = r'(x) + r'(p) + r'(g) - r(x) - r(p) - r(g)$$

$$= r'(p) + r'(g) - r(x) - r(p)$$

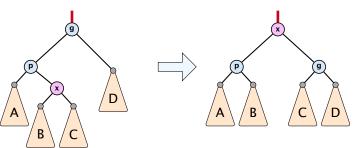

$$\leq r'(x) + r'(g) - r(x) - r(x)$$

$$= r'(x) + r'(g) + r(x) - 3r'(x) + 3r'(x) - r(x) - 2r(x)$$

$$= -2r'(x) + r'(g) + r(x) + 3(r'(x) - r(x))$$

$$\leq -2 + 3(r'(x) - r(x)) \Rightarrow \cos t_{zigzig} \leq 3(r'(x) - r(x))$$

# **Splay: Zigzag Case**

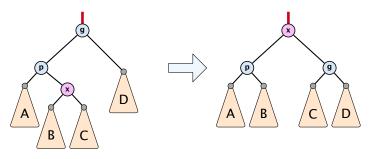

$$\begin{split} \Delta \Phi &= r'(x) + r'(p) + r'(g) - r(x) - r(p) - r(g) \\ &= r'(p) + r'(g) - r(x) - r(p) \\ &\leq r'(p) + r'(g) - r(x) - r(x) \\ &= r'(p) + r'(g) - 2r'(x) + 2r'(x) - 2r(x) \\ &\leq -2 + 2(r'(x) - r(x)) \quad \Rightarrow \text{cost}_{\text{zigzag}} \leq 3(r'(x) - r(x)) \end{split}$$

7.3 Splay Trees

9. Jan. 2023 **79/344** 

# Splay: Zigzag Case

$$\begin{split} &\frac{1}{2} \Big( r'(p) + r'(g) - 2 r'(x) \Big) \\ &= \frac{1}{2} \Big( \log(s'(p)) + \log(s'(g)) - 2 \log(s'(x)) \Big) \\ &\leq \log \Big( \frac{1}{2} \frac{s'(p)}{s'(x)} + \frac{1}{2} \frac{s'(g)}{s'(x)} \Big) \leq \log \Big( \frac{1}{2} \Big) = -1 \end{split}$$

Harald Räcke

7.3 Splay Trees

9. lan. 2023

9. Jan. 2023 81/344

79/344

#### Amortized cost of the whole splay operation:

$$\leq 1 + 1 + \sum_{\text{steps } t} 3(r_t(x) - r_{t-1}(x))$$

$$= 2 + 3(r(\text{root}) - r_0(x))$$

$$\leq \mathcal{O}(\log n)$$

The first one is added due to the fact that so far for each step of a splay-operation we have only counted the number of rotations, but the cost is 1+#rotations.

The second one comes from the zig-operation. Note that we have at most one zig-operation during a splay.

Harald Räcke

# 7.4 Augmenting Data Structures

#### Suppose you want to develop a data structure with:

- ► Insert(x): insert element x.
- **Search**(k): search for element with key k.
- **Delete**(x): delete element referenced by pointer x.
- find-by-rank( $\ell$ ): return the  $\ell$ -th element; return "error" if the data-structure contains less than ℓ elements.

Augment an existing data-structure instead of developing a new one.

## 7.4 Augmenting Data Structures

#### How to augment a data-structure

- 1. choose an underlying data-structure
- 2. determine additional information to be stored in the underlying structure
- 3. verify/show how the additional information can be maintained for the basic modifying operations on the underlying structure.
- 4. develop the new operations
- Of course, the above steps heavily depend on each other. For example it makes no sense to choose additional information to be stored (Step 2), and later realize that either the information cannot be maintained efficiently (Step 3) or is not sufficient to support the new operations (Step 4).
- However, the above outline is a good way to describe/document a new data-structure.

## 7.4 Augmenting Data Structures

Goal: Design a data-structure that supports insert, delete, search, and find-by-rank in time  $O(\log n)$ .

4. How does find-by-rank work? Find-by-rank(k) = Select(root,k) with

#### **Algorithm 1** Select(x, i)

- 1: **if** x = null **then return** error
- 2: **if** left[x]  $\neq$  null **then**  $r \leftarrow$  left[x]. size +1 **else**  $r \leftarrow$  1
- 3: if  $i = \gamma$  then return x
- 4: if  $i < \gamma$  then
- **return** Select(left[x], i)
- 6: else
- **return** Select(right[x], i r)

## 7.4 Augmenting Data Structures

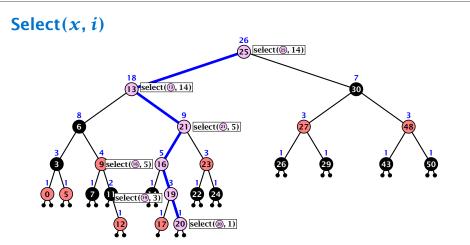

Goal: Design a data-structure that supports insert, delete, search, and find-by-rank in time  $O(\log n)$ .

- 1. We choose a red-black tree as the underlying data-structure.
- **2.** We store in each node v the size of the sub-tree rooted at v.
- 3. We need to be able to update the size-field in each node without asymptotically affecting the running time of insert, delete, and search. We come back to this step later...

Harald Räcke

7.4 Augmenting Data Structures

9. lan. 2023 83/344

#### Find-by-rank:

- decide whether you have to proceed into the left or right sub-tree
- adjust the rank that you are searching for if you go right

## 7.4 Augmenting Data Structures

Goal: Design a data-structure that supports insert, delete, search, and find-by-rank in time  $O(\log n)$ .

3. How do we maintain information?

**Search**(*k*): Nothing to do.

Insert(x): When going down the search path increase the size field for each visited node. Maintain the size field during rotations.

Delete(x): Directly after splicing out a node traverse the path from the spliced out node upwards, and decrease the size counter on every node on this path. Maintain the size field during rotations.

7.4 Augmenting Data Structures

9. lan. 2023 86/344

## **Augmenting Data Structures**

[CLRS90] Thomas H. Cormen, Charles E. Leiserson, Ron L. Rivest, Clifford Stein: Introduction to Algorithms (3rd ed.),

MIT Press and McGraw-Hill, 2009

See Chapter 14 of [CLRS90].

#### **Rotations**

The only operation during the fix-up procedure that alters the tree and requires an update of the size-field:

The nodes x and z are the only nodes changing their size-fields.

The new size-fields can be computed locally from the size-fields of the children.

# 7.5 Skip Lists

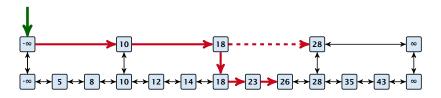

Why do we not use a list for implementing the ADT Dynamic Set?

- $\triangleright$  time for search  $\Theta(n)$
- $\blacktriangleright$  time for insert  $\Theta(n)$  (dominated by searching the item)
- $\blacktriangleright$  time for delete  $\Theta(1)$  if we are given a handle to the object, otw.  $\Theta(n)$

How can we improve the search-operation?

#### Add an express lane:

Let  $|L_1|$  denote the number of elements in the "express lane", and  $|L_0| = n$  the number of all elements (ignoring dummy elements).

Worst case search time:  $|L_1| + \frac{|L_0|}{|L_1|}$  (ignoring additive constants)

Choose  $|L_1| = \sqrt{n}$ . Then search time  $\Theta(\sqrt{n})$ .

## 7.5 Skip Lists

Choose ratios between list-lengths evenly, i.e.,  $\frac{|L_{i-1}|}{|L_i|} = r$ , and, hence,  $L_k \approx r^{-k}n$ .

Worst case running time is:  $O(r^{-k}n + kr)$ .

Choose  $r = n^{\frac{1}{k+1}}$ . Then

$$r^{-k}n + kr = \left(n^{\frac{1}{k+1}}\right)^{-k}n + kn^{\frac{1}{k+1}}$$
$$= n^{1-\frac{k}{k+1}} + kn^{\frac{1}{k+1}}$$
$$= (k+1)n^{\frac{1}{k+1}}.$$

Choosing  $k = \Theta(\log n)$  gives a logarithmic running time.

## 7.5 Skip Lists

Add more express lanes. Lane  $L_i$  contains roughly every  $\frac{L_{i-1}}{L_i}$ -th item from list  $L_{i-1}$ .

### Search(x) $(k + 1 \text{ lists } L_0, \ldots, L_k)$

- Find the largest item in list  $L_k$  that is smaller than x. At most  $|L_k| + 2$  steps.
- Find the largest item in list  $L_{k-1}$  that is smaller than x. At most  $\left\lceil \frac{|L_{k-1}|}{|L_k|+1} \right\rceil + 2$  steps.
- ▶ Find the largest item in list  $L_{k-2}$  that is smaller than x. At most  $\left\lceil \frac{|L_{k-2}|}{|L_{k-1}|+1} \right\rceil + 2$  steps.
- ▶ At most  $|L_k| + \sum_{i=1}^k \frac{L_{i-1}}{L_i} + 3(k+1)$  steps.

7.5 Skip Lists

9. Jan. 2023

90/344

# 7.5 Skip Lists

#### How to do insert and delete?

If we want that in  $L_i$  we always skip over roughly the same number of elements in  $L_{i-1}$  an insert or delete may require a lot of re-organisation.

Use randomization instead!

#### Insert:

- A search operation gives you the insert position for element x in every list.
- Flip a coin until it shows head, and record the number  $t \in \{1, 2, ...\}$  of trials needed.
- ▶ Insert x into lists  $L_0, \ldots, L_{t-1}$ .

#### Delete:

- ▶ You get all predecessors via backward pointers.
- $\triangleright$  Delete x in all lists it actually appears in.

The time for both operations is dominated by the search time.

7.5 Skip Lists

9. lan. 2023

93/344

# **High Probability**

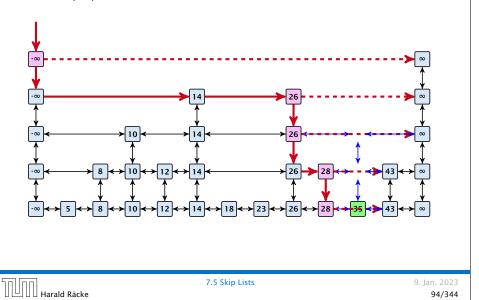

#### **Definition 7 (High Probability)**

We say a **randomized** algorithm has running time  $O(\log n)$  with high probability if for any constant  $\alpha$  the running time is at most  $\mathcal{O}(\log n)$  with probability at least  $1 - \frac{1}{n^{\alpha}}$ .

Here the  $\mathcal{O}$ -notation hides a constant that may depend on  $\alpha$ .

## 7.5 Skip Lists

Insert (35):

# **High Probability**

Suppose there are polynomially many events  $E_1, E_2, \dots, E_\ell, \ell = n^c$ each holding with high probability (e.g.  $E_i$  may be the event that the *i*-th search in a skip list takes time at most  $O(\log n)$ .

Then the probability that all  $E_i$  hold is at least

$$\Pr[E_1 \wedge \cdots \wedge E_{\ell}] = 1 - \Pr[\bar{E}_1 \vee \cdots \vee \bar{E}_{\ell}]$$

$$\geq 1 - n^c \cdot n^{-\alpha}$$

$$= 1 - n^{c-\alpha}.$$

This means  $Pr[E_1 \wedge \cdots \wedge E_\ell]$  holds with high probability.

94/344

#### Lemma 8

A search (and, hence, also insert and delete) in a skip list with n elements takes time O(logn) with high probability (w. h. p.).

7.5 Skip Lists

9. lan. 2023

97/344

## 7.5 Skip Lists

#### **Estimation for Binomial Coefficients**

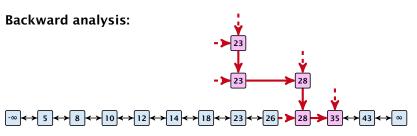

$$\left(\frac{n}{k}\right)^k \le \binom{n}{k} \le \left(\frac{en}{k}\right)^k$$

$$\binom{n}{k} = \frac{n!}{k! \cdot (n-k)!} = \frac{n \cdot \ldots \cdot (n-k+1)}{k \cdot \ldots \cdot 1} \ge \left(\frac{n}{k}\right)^k$$

$$\binom{n}{k} = \frac{n \cdot \dots \cdot (n-k+1)}{k!} \le \frac{n^k}{k!} = \frac{n^k \cdot k^k}{k^k \cdot k!}$$
$$= \left(\frac{n}{k}\right)^k \cdot \frac{k^k}{k!} \le \left(\frac{n}{k}\right)^k \cdot \sum_{i>0} \frac{k^i}{i!} = \left(\frac{en}{k}\right)^k$$

## 7.5 Skip Lists

# **Backward analysis:**

At each point the path goes up with probability 1/2 and left with probability 1/2.

We show that w.h.p:

- A "long" search path must also go very high.
- ► There are no elements in high lists.

From this it follows that w.h.p. there are no long paths.

7.5 Skip Lists

9. Jan. 2023

98/344

# 7.5 Skip Lists

Let  $E_{z,k}$  denote the event that a search path is of length z(number of edges) but does not visit a list above  $L_k$ .

In particular, this means that during the construction in the backward analysis we see at most k heads (i.e., coin flips that tell you to go up) in z trials.

9. Jan. 2023 100/344

 $Pr[E_{z,k}] \leq Pr[at most k heads in z trials]$ 

$$\leq \binom{z}{k} 2^{-(z-k)} \leq \left(\frac{ez}{k}\right)^k 2^{-(z-k)} \leq \left(\frac{2ez}{k}\right)^k 2^{-z}$$

choosing  $k = \gamma \log n$  with  $\gamma \ge 1$  and  $z = (\beta + \alpha)\gamma \log n$ 

$$\leq \left(\frac{2ez}{k}\right)^k 2^{-\beta k} \cdot n^{-\gamma \alpha} \leq \left(\frac{2ez}{2^{\beta}k}\right)^k \cdot n^{-\alpha}$$
$$\leq \left(\frac{2e(\beta + \alpha)}{2^{\beta}}\right)^k n^{-\alpha}$$

now choosing  $\beta = 6\alpha$  gives

$$\leq \left(\frac{42\alpha}{64^{\alpha}}\right)^k n^{-\alpha} \leq n^{-\alpha}$$

for  $\alpha \geq 1$ .

7.5 Skip Lists

9. lan. 2023 101/344

# **Skip Lists**

#### Bibliography

[GT98] Michael T. Goodrich, Roberto Tamassia Data Structures and Algorithms in JAVA, John Wiley, 1998

Skip lists are covered in Chapter 7.5 of [GT98].

## 7.5 Skip Lists

So far we fixed  $k = \gamma \log n$ ,  $\gamma \ge 1$ , and  $z = 7\alpha \gamma \log n$ ,  $\alpha \ge 1$ .

This means that a search path of length  $\Omega(\log n)$  visits a list on a level  $\Omega(\log n)$ , w.h.p.

Let  $A_{k+1}$  denote the event that the list  $L_{k+1}$  is non-empty. Then

$$\Pr[A_{k+1}] \le n2^{-(k+1)} \le n^{-(\gamma-1)}$$
.

For the search to take at least  $z = 7\alpha y \log n$  steps either the event  $E_{z,k}$  or the event  $A_{k+1}$  must hold. Hence.

$$\Pr[\text{search requires } z \text{ steps}] \le \Pr[E_{z,k}] + \Pr[A_{k+1}]$$
  
 $\le n^{-\alpha} + n^{-(\gamma-1)}$ 

This means, the search requires at most z steps, w. h. p.

#### 7.6 van Emde Boas Trees

#### Dynamic Set Data Structure S:

- $\triangleright$  S.insert(x)
- $\triangleright$  S. delete(x)
- $\triangleright$  S. search(x)
- ► *S*. min()
- ► S. max()
- $\triangleright$  S. succ(x)
- $\triangleright$  S. pred(x)

#### 7.6 van Emde Boas Trees

For this chapter we ignore the problem of storing satellite data:

- $\triangleright$  S. insert(x): Inserts x into S.
- ▶ S. delete(x): Deletes x from S. Usually assumes that  $x \in S$ .
- **S.** member(x): Returns 1 if  $x \in S$  and 0 otw.
- ► S. min(): Returns the value of the minimum element in S.
- **S.** max(): Returns the value of the maximum element in S.
- $\triangleright$  S. succ(x): Returns successor of x in S. Returns null if x is maximum or larger than any element in S. Note that x needs not to be in S.
- S. pred(x): Returns the predecessor of x in S. Returns null if x is minimum or smaller than any element in S. Note that x needs not to be in S.

108/344

# **Implementation 2: Summary Array**

- $ightharpoonup \sqrt{u}$  cluster-arrays of  $\sqrt{u}$  bits.
- One summary-array of  $\sqrt{u}$  bits. The i-th bit in the summary array stores the bit-wise or of the bits in the i-th cluster.

## **Implementation 1: Array**

#### **Algorithm 6** array.succ(x)

- 1: **for** (i = x + 1; i < size; i++) **do**
- 2: **if** content[i] = 1 **then return** i;
- 3: return null;

#### **Algorithm 7** array.pred(x)

- 1: **for**  $(i = x 1; i \ge 0; i--)$  **do**
- 2: **if** content[i] = 1 **then return** i;
- 3: **return** null;
- ightharpoonup Running time is  $\mathcal{O}(u)$  in the worst case.

7.6 van Emde Boas Trees

9. Jan. 2023

109/344

# **Implementation 2: Summary Array**

The bit for a key x is contained in cluster number  $\left|\frac{x}{\sqrt{y}}\right|$ .

Within the cluster-array the bit is at position  $x \mod \sqrt{u}$ .

For simplicity we assume that  $u=2^{2k}$  for some  $k\geq 1$ . Then we can compute the cluster-number for an entry x as  $\mathrm{high}(x)$  (the upper half of the dual representation of x) and the position of x within its cluster as  $\mathrm{low}(x)$  (the lower half of the dual representation).

# **Implementation 2: Summary Array**

# Algorithm 8 member(x) 1: **return** cluster[high(x)]. member(low(x));

```
Algorithm 9 insert(x)

1: cluster[high(x)].insert(low(x));
2: summary.insert(high(x));
```

► The running times are constant, because the corresponding array-functions have constant running times.

Harald Räcke

7.6 van Emde Boas Trees

9. Jan. 2023 112/344

The operator o stands

for the concatenation

of two bitstrings.

This means if

 $x = 0111_2$  and

 $\nu = 0001_{2} \text{ then}$ 

 $x \circ y = 01110001_2$ .

# **Implementation 2: Summary Array**

## Algorithm 11 max()

- 1: *maxcluster* ← summary.max();
- 2: **if** *maxcluster* = null **return** null;
- 3:  $offs \leftarrow cluster[maxcluster].max()$
- 4: **return** *maxcluster* ∘ *offs*;

## Algorithm 12 min()

- 1: *mincluster* ← summary.min();
- 2: **if** *mincluster* = null **return** null;
- 3:  $offs \leftarrow cluster[mincluster].min();$
- 4: **return** *mincluster offs*;
- ▶ Running time is roughly  $2\sqrt{u} = \mathcal{O}(\sqrt{u})$  in the worst case.

# **Implementation 2: Summary Array**

#### **Algorithm 10** delete(x)

- 1: cluster[high(x)]. delete(low(x));
- 2: **if** cluster[high(x)].min() = null **then**
- 3: summary.delete(high(x));
- The running time is dominated by the cost of a minimum computation on an array of size  $\sqrt{u}$ . Hence,  $\mathcal{O}(\sqrt{u})$ .

Harald Räcke

7.6 van Emde Boas Trees

9. Jan. 2023 113/344

# **Implementation 2: Summary Array**

#### Algorithm 13 succ(x)

- 1:  $m \leftarrow \text{cluster}[\text{high}(x)]. \text{succ}(\text{low}(x))$
- 2: **if**  $m \neq \text{null}$  **then return**  $\text{high}(x) \circ m$ ;
- 3:  $succeluster \leftarrow summary.succ(high(x));$
- 4: **if** *succcluster* ≠ null **then**
- 5:  $offs \leftarrow cluster[succeluster].min();$
- 6: **return** *succeluster* ∘ *offs*;
- 7: return null;
- Running time is roughly  $3\sqrt{u} = \mathcal{O}(\sqrt{u})$  in the worst case.

## **Implementation 2: Summary Array**

```
Algorithm 14 pred(x)
1: m \leftarrow \text{cluster}[\text{high}(x)]. \text{pred}(\text{low}(x))
2: if m \neq \text{null} then return \text{high}(x) \circ m;
3: predcluster \leftarrow summary.pred(high(x));
4: if predcluster ≠ null then
         offs \leftarrow cluster[predcluster].max();
         return predcluster ∘ offs;
7: return null;
```

▶ Running time is roughly  $3\sqrt{u} = \mathcal{O}(\sqrt{u})$  in the worst case.

7.6 van Emde Boas Trees

9. lan. 2023 116/344

# **Implementation 3: Recursion**

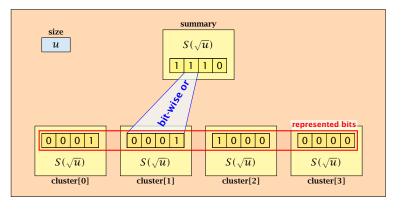

We assume that  $u = 2^{2^k}$  for some k.

The data-structure S(2) is defined as an array of 2-bits (end of the recursion).

## **Implementation 3: Recursion**

Instead of using sub-arrays, we build a recursive data-structure.

S(u) is a dynamic set data-structure representing u bits:

Harald Räcke

7.6 van Emde Boas Trees

9. lan. 2023 117/344

# **Implementation 3: Recursion**

The code from Implementation 2 can be used unchanged. We only need to redo the analysis of the running time.

Note that in the code we do not need to specifically address the non-recursive case. This is achieved by the fact that an S(4) will contain S(2)'s as sub-datastructures, which are arrays. Hence, a call like cluster[1].min() from within the data-structure S(4) is not a recursive call as it will call the function array.min().

This means that the non-recursive case is been dealt with while initializing the data-structure.

# **Implementation 3: Recursion**

Algorithm 15 member(x)

1: **return** cluster[high(x)].member(low(x));

 $T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1.$ 

Harald Räcke

9. Jan. 2023

120/344

# **Implementation 3: Recursion**

Algorithm 16 insert(x)

1: cluster[high(x)].insert(low(x));

2: summary.insert(high(x));

 $T_{ins}(u) = 2T_{ins}(\sqrt{u}) + 1.$ 

Harald Räcke

7.6 van Emde Boas Trees

9. Jan. 2023 121/344

## **Implementation 3: Recursion**

Algorithm 17 delete(x)

1:  $\operatorname{cluster}[\operatorname{high}(x)]$ .  $\operatorname{delete}(\operatorname{low}(x))$ ;

2: **if** cluster[high(x)].min() = null **then** 

3: summary.delete(high(x));

 $T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1.$ 

# **Implementation 3: Recursion**

Algorithm 18 min()

1: *mincluster* ← summary.min();

2: **if** *mincluster* = null **return** null;

3:  $offs \leftarrow cluster[mincluster].min();$ 

4: **return** *mincluster* ∘ *offs*;

 $T_{\min}(u) = 2T_{\min}(\sqrt{u}) + 1.$ 

## **Implementation 3: Recursion**

#### Algorithm 19 succ(x)

1:  $m \leftarrow \text{cluster}[\text{high}(x)]. \text{succ}(\text{low}(x))$ 

2: **if**  $m \neq \text{null then return high}(x) \circ m$ ;

3:  $succeluster \leftarrow summary.succ(high(x));$ 

4: **if** *succcluster* ≠ null **then** 

5: *offs* ← cluster[*succcluster*].min();

6: **return** *succeluster* ∘ *offs*;

7: return null;

 $T_{\text{Succ}}(u) = 2T_{\text{Succ}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1.$ 

7.6 van Emde Boas Trees

9. Jan. 2023

124/344

## **Implementation 3: Recursion**

$$T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$$
:

Set  $\ell := \log u$  and  $X(\ell) := T_{\text{mem}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{mem}}(2^{\ell}) = T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$$
  
=  $T_{\text{mem}}(2^{\frac{\ell}{2}}) + 1 = X(\frac{\ell}{2}) + 1$ .

Using Master theorem gives  $X(\ell) = \mathcal{O}(\log \ell)$ , and hence  $T_{\text{mem}}(u) = \mathcal{O}(\log \log u)$ .

7.6 van Emde Boas Trees

9. Jan. 2023

125/344

## **Implementation 3: Recursion**

$$T_{\rm ins}(u) = 2T_{\rm ins}(\sqrt{u}) + 1.$$

Set  $\ell := \log u$  and  $X(\ell) := T_{\text{ins}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{ins}}(2^{\ell}) = T_{\text{ins}}(u) = 2T_{\text{ins}}(\sqrt{u}) + 1$$
$$= 2T_{\text{ins}}(2^{\frac{\ell}{2}}) + 1 = 2X(\frac{\ell}{2}) + 1 .$$

Using Master theorem gives  $X(\ell) = \mathcal{O}(\ell)$ , and hence  $T_{\text{ins}}(u) = \mathcal{O}(\log u)$ .

The same holds for  $T_{\text{max}}(u)$  and  $T_{\text{min}}(u)$ .

# **Implementation 3: Recursion**

$$T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1 \le 2T_{\text{del}}(\sqrt{u}) + c \log(u).$$

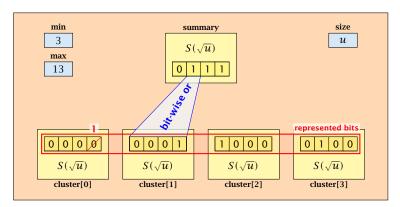

Set  $\ell := \log u$  and  $X(\ell) := T_{\text{del}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{del}}(2^{\ell}) = T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + c \log u$$
$$= 2T_{\text{del}}(2^{\frac{\ell}{2}}) + c\ell = 2X(\frac{\ell}{2}) + c\ell .$$

Using Master theorem gives  $X(\ell) = \Theta(\ell \log \ell)$ , and hence  $T_{\text{del}}(u) = \mathcal{O}(\log u \log \log u)$ .

The same holds for  $T_{\text{pred}}(u)$  and  $T_{\text{succ}}(u)$ .

## **Implementation 4: van Emde Boas Trees**

- ► The bit referenced by min is not set within sub-datastructures.
- ▶ The bit referenced by max is set within sub-datastructures (if  $\max \neq \min$ ).

Harald Räcke

7.6 van Emde Boas Trees

9. lan. 2023 128/344

1: return min;

Constant time.

## **Implementation 4: van Emde Boas Trees**

#### Advantages of having max/min pointers:

- ▶ Recursive calls for min and max are constant time.
- ▶ min = null means that the data-structure is empty.
- $ightharpoonup min = max \neq null$  means that the data-structure contains exactly one element.
- ▶ We can insert into an empty datastructure in constant time by only setting  $\min = \max = x$ .
- ▶ We can delete from a data-structure that just contains one element in constant time by setting min = max = null.

## Implementation 4: van Emde Boas Trees

Note that the recusive call in Line 7 takes constant time as the if-condition in Line 5 ensures that we are inserting in an empty sub-tree.

The only non-constant recursive calls are the call in Line 6 and in Line 9. These are mutually exclusive, i.e., only one of these calls will actually occur.

From this we get that  $T_{\text{ins}}(u) = T_{\text{ins}}(\sqrt{u}) + 1$ .

## **Implementation 4: van Emde Boas Trees**

```
Algorithm 35 insert(x)

1: if min = null then

2: min = x; max = x;

3: else

4: if x < \min then exchange x and min;

5: if x > \max then max = x;

6: if cluster[high(x)]. min = null; then

7: summary.insert(high(x));

8: cluster[high(x)]. insert(low(x));

9: else

10: cluster[high(x)]. insert(low(x));
```

 $T_{\text{ins}}(u) = T_{\text{ins}}(\sqrt{u}) + 1 \Longrightarrow T_{\text{ins}}(u) = \mathcal{O}(\log \log u).$

#### 7.6 van Emde Boas Trees

#### **Space requirements:**

► The space requirement fulfills the recurrence

$$S(u) = (\sqrt{u} + 1)S(\sqrt{u}) + O(\sqrt{u})$$
.

- Note that we cannot solve this recurrence by the Master theorem as the branching factor is not constant.
- ▶ One can show by induction that the space requirement is  $S(u) = \mathcal{O}(u)$ . Exercise.

## **Implementation 4: van Emde Boas Trees**

Note that only one of the possible recusive calls in Line 9 and Line 11 in the deletion-algorithm may take non-constant time.

To see this observe that the call in Line 11 only occurs if the cluster where x was deleted is now empty. But this means that the call in Line 9 deleted the last element in cluster [high(x)]. Such a call only takes constant time.

Hence, we get a recurrence of the form

$$T_{\rm del}(u) = T_{\rm del}(\sqrt{u}) + c$$
.

This gives  $T_{\text{del}}(u) = \mathcal{O}(\log \log u)$ .

Harald Räcke

7.6 van Emde Boas Trees

9. Jan. 2023 137/344

▶ Let the "real" recurrence relation be

$$S(k^2) = (k+1)S(k) + c_1 \cdot k; S(4) = c_2$$

▶ Replacing S(k) by  $R(k) := S(k)/c_2$  gives the recurrence

$$R(k^2) = (k+1)R(k) + ck$$
;  $R(4) = 1$ 

where  $c = c_1/c_2 < 1$ .

- Now, we show  $R(k^2) \le k^2 2$  for  $k^2 \ge 4$ .
  - Obviously, this holds for  $k^2 = 4$ .
  - For  $k^2 > 4$  we have

$$R(k^{2}) = (1+k)R(k) + ck$$
  

$$\leq (1+k)(k-2) + k \leq k^{2} - 2$$

▶ This shows that R(k) and, hence, S(k) grows linearly.

# 7.7 Hashing

#### **Definitions:**

- ▶ Universe U of keys, e.g.,  $U \subseteq \mathbb{N}_0$ . U very large.
- ▶ Set  $S \subseteq U$  of keys,  $|S| = m \le |U|$ .
- ▶ Array T[0,...,n-1] hash-table.
- ► Hash function  $h: U \rightarrow [0, ..., n-1]$ .

#### The hash-function h should fulfill:

- Fast to evaluate.
- Small storage requirement.
- ▶ Good distribution of elements over the whole table.

## 7.7 Hashing

#### **Dictionary:**

- $\triangleright$  S. insert(x): Insert an element x.
- **S.** delete(x): Delete the element pointed to by x.
- ▶ *S.* search(k): Return a pointer to an element e with key[e] = k in S if it exists; otherwise return null.

So far we have implemented the search for a key by carefully choosing split-elements.

Then the memory location of an object x with key k is determined by successively comparing k to split-elements.

Hashing tries to directly compute the memory location from the given key. The goal is to have constant search time.

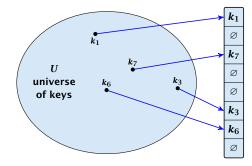

7.7 Hashing

9. Jan. 2023 140/344

## **Direct Addressing**

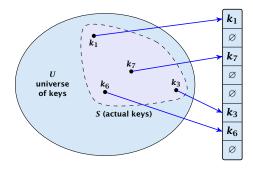

Ideally the hash function maps all keys to different memory locations.

This special case is known as Direct Addressing. It is usually very unrealistic as the universe of keys typically is quite large, and in particular larger than the available memory.

## **Perfect Hashing**

Suppose that we know the set S of actual keys (no insert/no delete). Then we may want to design a simple hash-function that maps all these keys to different memory locations.

Such a hash function h is called a perfect hash function for set S.

7.7 Hashing

9. lan. 2023

143/344

#### **Collisions**

Typically, collisions do not appear once the size of the set *S* of actual keys gets close to n, but already when  $|S| \ge \omega(\sqrt{n})$ .

#### Lemma 9

into a table of size n under uniform hashing is at least

$$1 - e^{-\frac{m(m-1)}{2n}} \approx 1 - e^{-\frac{m^2}{2n}}$$
.

#### Uniform hashing:

Choose a hash function uniformly at random from all functions  $f: U \to [0, ..., n-1].$ 

#### **Collisions**

If we do not know the keys in advance, the best we can hope for is that the hash function distributes keys evenly across the table.

#### **Problem: Collisions**

Usually the universe U is much larger than the table-size n.

Hence, there may be two elements  $k_1, k_2$  from the set S that map to the same memory location (i.e.,  $h(k_1) = h(k_2)$ ). This is called a collision.

7.7 Hashing

9. lan. 2023 144/344

The probability of having a collision when hashing m elements

## **Collisions**

#### Proof.

Let  $A_{m,n}$  denote the event that inserting m keys into a table of size n does not generate a collision. Then

$$\Pr[A_{m,n}] = \prod_{\ell=1}^{m} \frac{n-\ell+1}{n} = \prod_{j=0}^{m-1} \left(1 - \frac{j}{n}\right)$$

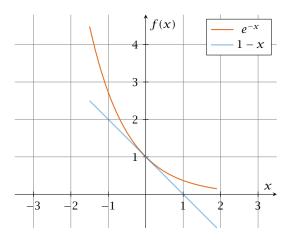

$$\leq \prod_{j=0}^{m-1} e^{-j/n} = e^{-\sum_{j=0}^{m-1} \frac{j}{n}} = e^{-\frac{m(m-1)}{2n}} .$$

Here the first equality follows since the  $\ell$ -th element that is hashed has a probability of  $\frac{n-\ell+1}{n}$  to not generate a collision under the condition that the previous elements did not induce collisions.

9. lan. 2023

145/344

#### **Collisions**

The inequality  $1 - x \le e^{-x}$  is derived by stopping the Taylor-expansion of  $e^{-x}$  after the second term.

Harald Räcke

7.7 Hashing

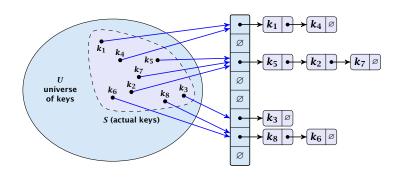

9. Jan. 2023

147/344

# **Hashing with Chaining**

Arrange elements that map to the same position in a linear list.

- Access: compute h(x) and search list for key[x].
- Insert: insert at the front of the list.

## **Resolving Collisions**

The methods for dealing with collisions can be classified into the two main types

- open addressing, aka. closed hashing
- hashing with chaining, aka. closed addressing, open hashing.

There are applications e.g. computer chess where you do not resolve collisions at all.

Harald Räcke

7.7 Hashing

9. Jan. 2023 148/344

### Hashing with Chaining

Let A denote a strategy for resolving collisions. We use the following notation:

- ▶  $A^+$  denotes the average time for a **successful** search when using A;
- ►  $A^-$  denotes the average time for an **unsuccessful** search when using A;
- We parameterize the complexity results in terms of  $\alpha := \frac{m}{n}$ , the so-called fill factor of the hash-table.

We assume uniform hashing for the following analysis.

9. Jan. 2023 149/344

# **Hashing with Chaining**

The time required for an unsuccessful search is 1 plus the length of the list that is examined. The average length of a list is  $\alpha = \frac{m}{n}$ . Hence, if A is the collision resolving strategy "Hashing with Chaining" we have

$$A^- = 1 + \alpha .$$

Harald Räcke

7.7 Hashing

9. Jan. 2023

151/344

## **Hashing with Chaining**

$$E\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right] = \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}E\left[X_{ij}\right]\right)$$

$$= \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}\frac{1}{n}\right)$$

$$= 1+\frac{1}{mn}\sum_{i=1}^{m}(m-i)$$

$$= 1+\frac{1}{mn}\left(m^{2}-\frac{m(m+1)}{2}\right)$$

$$= 1+\frac{m-1}{2n}=1+\frac{\alpha}{2}-\frac{\alpha}{2m}.$$

Hence, the expected cost for a successful search is  $A^+ \leq 1 + \frac{\alpha}{2}$ .

#### Hashing with Chaining

For a successful search observe that we do **not** choose a list at random, but we consider a random key k in the hash-table and ask for the search-time for k.

This is 1 plus the number of elements that lie before *k* in *k*'s list.

Let  $k_{\ell}$  denote the  $\ell$ -th key inserted into the table.

Let for two keys  $k_i$  and  $k_j$ ,  $X_{ij}$  denote the indicator variable for the event that  $k_i$  and  $k_j$  hash to the same position. Clearly,  $\Pr[X_{ij} = 1] = 1/n$  for uniform hashing.

The expected successful search cost is

Estimated the cost is keys before  $k_i$   $\mathbb{E}\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right]$ cost for key  $k_i$ 

7.7 Hashing

9. Jan. 2023

152/344

# **Hashing with Chaining**

#### Disadvantages:

- pointers increase memory requirements
- pointers may lead to bad cache efficiency

#### Advantages:

- no à priori limit on the number of elements
- deletion can be implemented efficiently
- by using balanced trees instead of linked list one can also obtain worst-case guarantees.

## **Open Addressing**

All objects are stored in the table itself.

Define a function h(k, j) that determines the table-position to be examined in the *j*-th step. The values  $h(k,0),\ldots,h(k,n-1)$ must form a permutation of  $0, \ldots, n-1$ .

**Search**(k): Try position h(k, 0); if it is empty your search fails; otw. continue with h(k,1), h(k,2), ....

**Insert**(x): Search until you find an empty slot; insert your element there. If your search reaches h(k, n-1), and this slot is non-empty then your table is full.

7.7 Hashing

9. lan. 2023 155/344

9. Ian. 2023

157/344

#### **Linear Probing**

- Advantage: Cache-efficiency. The new probe position is very likely to be in the cache.
- Disadvantage: Primary clustering. Long sequences of occupied table-positions get longer as they have a larger probability to be hit. Furthermore, they can merge forming larger sequences.

#### Lemma 10

Let L be the method of linear probing for resolving collisions:

$$L^+ \approx \frac{1}{2} \left( 1 + \frac{1}{1 - \alpha} \right)$$

$$L^- \approx \frac{1}{2} \left( 1 + \frac{1}{(1 - \alpha)^2} \right)$$

### **Open Addressing**

Choices for h(k, j):

- Linear probing:  $h(k, i) = h(k) + i \mod n$ (sometimes:  $h(k, i) = h(k) + ci \mod n$ ).
- Quadratic probing:  $h(k,i) = h(k) + c_1 i + c_2 i^2 \mod n$ .
- ► Double hashing:  $h(k,i) = h_1(k) + ih_2(k) \mod n$ .

For quadratic probing and double hashing one has to ensure that the search covers all positions in the table (i.e., for double hashing  $h_2(k)$  must be relatively prime to n (teilerfremd); for quadratic probing  $c_1$  and  $c_2$  have to be chosen carefully).

7.7 Hashing

9. Ian. 2023

156/344

# **Quadratic Probing**

- Not as cache-efficient as Linear Probing.
- Secondary clustering: caused by the fact that all keys mapped to the same position have the same probe sequence.

#### Lemma 11

Let Q be the method of quadratic probing for resolving collisions:

$$Q^{+} \approx 1 + \ln\left(\frac{1}{1-\alpha}\right) - \frac{\alpha}{2}$$

$$Q^- \approx \frac{1}{1-\alpha} + \ln\left(\frac{1}{1-\alpha}\right) - \alpha$$

7.7 Hashing

# **Double Hashing**

▶ Any probe into the hash-table usually creates a cache-miss.

#### Lemma 12

Let D be the method of double hashing for resolving collisions:

$$D^+ \approx \frac{1}{\alpha} \ln \left( \frac{1}{1 - \alpha} \right)$$

$$D^- \approx \frac{1}{1-\alpha}$$

The j-th rectangle appears in both sums  $j^6$  times. (j times in the first due to multiplication with j; and j times in the second for summands i = 1, 2, ..., j

# **Analysis of Idealized Open Address Hashing**

i = 4

The j-th rectangle appears in both sums  $j^6$  times. (j times in the first due to multiplication with j; and j times in the second for summands  $i = 1, 2, \dots, j$ 

9. lan. 2023

165/344

## **Analysis of Idealized Open Address Hashing**

The number of probes in a successful search for k is equal to the number of probes made in an unsuccessful search for k at the time that k is inserted.

Let k be the i+1-st element. The expected time for a search for kis at most  $\frac{1}{1-i/n} = \frac{n}{n-i}$ .

$$\frac{1}{m} \sum_{i=0}^{m-1} \frac{n}{n-i} = \frac{n}{m} \sum_{i=0}^{m-1} \frac{1}{n-i} = \frac{1}{\alpha} \sum_{k=n-m+1}^{n} \frac{1}{k}$$

$$\leq \frac{1}{\alpha} \int_{n-m}^{n} \frac{1}{x} dx = \frac{1}{\alpha} \ln \frac{n}{n-m} = \frac{1}{\alpha} \ln \frac{1}{1-\alpha} .$$

7.7 Hashing

9. lan. 2023 166/344

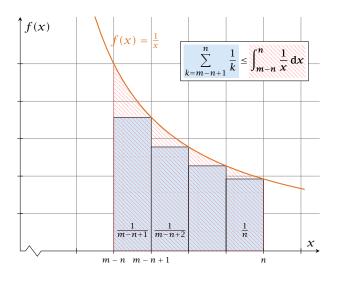

> 9. Ian. 2023 168/344

#### **Deletions in Hashtables**

#### How do we delete in a hash-table?

- For hashing with chaining this is not a problem. Simply search for the key, and delete the item in the corresponding list.
- For open addressing this is difficult.

## **Analysis of Idealized Open Address Hashing**

Harald Räcke

7.7 Hashing

9. Ian. 2023 167/344

169/344

#### **Deletions in Hashtables**

- Simply removing a key might interrupt the probe sequence of other keys which then cannot be found anymore.
- One can delete an element by replacing it with a deleted-marker.
  - During an insertion if a deleted-marker is encountered an element can be inserted there.
  - During a search a deleted-marker must not be used to terminate the probe sequence.
- ▶ The table could fill up with deleted-markers leading to bad performance.
- If a table contains many deleted-markers (linear fraction of the keys) one can rehash the whole table and amortize the cost for this rehash against the cost for the deletions.

# **Deletions for Linear Probing**

- ► For Linear Probing one can delete elements without using deletion-markers.
- ▶ Upon a deletion elements that are further down in the probe-sequence may be moved to guarantee that they are still found during a search.

7.7 Hashing

9. Jan. 2023

170/344

## **Universal Hashing**

Regardless, of the choice of hash-function there is always an input (a set of keys) that has a very poor worst-case behaviour.

Therefore, so far we assumed that the hash-function is random so that regardless of the input the average case behaviour is good.

However, the assumption of uniform hashing that h is chosen randomly from all functions  $f:U\to [0,\dots,n-1]$  is clearly unrealistic as there are  $n^{|U|}$  such functions. Even writing down such a function would take  $|U|\log n$  bits.

Universal hashing tries to define a set  $\mathcal H$  of functions that is much smaller but still leads to good average case behaviour when selecting a hash-function uniformly at random from  $\mathcal H$ .

# **Deletions for Linear Probing**

#### Algorithm 37 delete(p)

- 1:  $T[p] \leftarrow \text{null}$
- 2:  $p \leftarrow \operatorname{succ}(p)$
- 3: while  $T[p] \neq \text{null do}$
- 4:  $y \leftarrow T[p]$
- $T[p] \leftarrow \text{null}$
- 6:  $p \leftarrow \operatorname{succ}(p)$
- 7: insert(y)

p is the index into the table-cell that contains the object to be deleted.

Pointers into the hash-table become invalid.

7.7 Hashing

9. Jan. 2023

171/344

# **Universal Hashing**

#### **Definition 13**

A class  $\mathcal H$  of hash-functions from the universe U into the set  $\{0,\ldots,n-1\}$  is called universal if for all  $u_1,u_2\in U$  with  $u_1\neq u_2$ 

$$\Pr[h(u_1) = h(u_2)] \le \frac{1}{n} ,$$

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

Note that this means that the probability of a collision between two arbitrary elements is at most  $\frac{1}{n}$ .

#### **Definition 14**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \dots, n-1\}$  is called 2-independent (pairwise independent) if the following two conditions hold

- For any key  $u \in U$ , and  $t \in \{0, ..., n-1\}$   $\Pr[h(u) = t] = \frac{1}{n}$ , i.e., a key is distributed uniformly within the hash-table.
- For all  $u_1, u_2 \in U$  with  $u_1 \neq u_2$ , and for any two hash-positions  $t_1, t_2$ :

$$\Pr[h(u_1) = t_1 \land h(u_2) = t_2] \le \frac{1}{n^2} .$$

This requirement clearly implies a universal hash-function.

7.7 Hashing

9. lan. 2023

174/344

### **Universal Hashing**

#### **Definition 16**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0,\ldots,n-1\}$  is called  $(\mu,k)$ -independent if for any choice of  $\ell \leq k$  distinct keys  $u_1, \ldots, u_\ell \in U$ , and for any set of  $\ell$  not necessarily distinct hash-positions  $t_1, \ldots, t_\ell$ :

$$\Pr[h(u_1) = t_1 \wedge \cdots \wedge h(u_\ell) = t_\ell] \leq \frac{\mu}{n^\ell} ,$$

where the probability is w. r. t. the choice of a random hash-function from set  $\mathcal{H}$ .

## **Universal Hashing**

#### **Definition 15**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0,\ldots,n-1\}$  is called *k*-independent if for any choice of  $\ell \leq k$ distinct keys  $u_1, \ldots, u_\ell \in U$ , and for any set of  $\ell$  not necessarily distinct hash-positions  $t_1, \ldots, t_\ell$ :

$$\Pr[h(u_1) = t_1 \wedge \cdots \wedge h(u_{\ell}) = t_{\ell}] \leq \frac{1}{n\ell} ,$$

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

Let  $U := \{0, \dots, p-1\}$  for a prime p. Let  $\mathbb{Z}_p := \{0, \dots, p-1\}$ , and let  $\mathbb{Z}_{p}^{*} := \{1, \dots, p-1\}$  denote the set of invertible elements in  $\mathbb{Z}_{p}$ .

Define

$$h_{a,b}(x) := (ax + b \bmod p) \bmod n$$

#### Lemma 17

The class

$$\mathcal{H} = \{h_{a,b} \mid a \in \mathbb{Z}_n^*, b \in \mathbb{Z}_n\}$$

is a universal class of hash-functions from U to  $\{0, \ldots, n-1\}$ .

#### Proof.

Let  $x, y \in U$  be two distinct keys. We have to show that the probability of a collision is only 1/n.

 $ightharpoonup ax + b \not\equiv ay + b \pmod{p}$ 

If  $x \neq y$  then  $(x - y) \not\equiv 0 \pmod{p}$ .

Multiplying with  $a \not\equiv 0 \pmod{p}$  gives

$$a(x - y) \not\equiv 0 \pmod{p}$$

where we use that  $\mathbb{Z}_p$  is a field (Körper) and, hence, has no zero divisors (nullteilerfrei).

7.7 Hashing

9. Jan. 2023 178/344

# **Universal Hashing**

There is a one-to-one correspondence between hash-functions (pairs (a,b),  $a \ne 0$ ) and pairs  $(t_x,t_y)$ ,  $t_x \ne t_y$ .

Therefore, we can view the first step (before the mod n-operation) as choosing a pair  $(t_x, t_y)$ ,  $t_x \neq t_y$  uniformly at random.

What happens when we do the mod n operation?

Fix a value  $t_x$ . There are p-1 possible values for choosing  $t_y$ .

From the range 0, ..., p-1 the values  $t_x, t_x + n, t_x + 2n, ...$  map to  $t_x$  after the modulo-operation. These are at most  $\lceil p/n \rceil$  values.

## **Universal Hashing**

► The hash-function does not generate collisions before the (mod n)-operation. Furthermore, every choice (a,b) is mapped to a different pair  $(t_x,t_y)$  with  $t_x:=ax+b$  and  $t_y:=ay+b$ .

This holds because we can compute a and b when given  $t_x$  and  $t_y$ :

$$t_x \equiv ax + b \pmod{p}$$

$$t_{\mathcal{V}} \equiv ay + b \pmod{p}$$

$$t_X - t_Y \equiv a(X - Y) \tag{mod } p)$$

$$t_{\mathcal{V}} \equiv a\mathcal{Y} + b \pmod{p}$$

$$a \equiv (t_X - t_Y)(x - y)^{-1} \pmod{p}$$

$$b \equiv t_{\mathcal{V}} - a_{\mathcal{V}} \tag{mod } p)$$

## **Universal Hashing**

As  $t_y \neq t_x$  there are

$$\left\lceil \frac{p}{n} \right\rceil - 1 \le \frac{p}{n} + \frac{n-1}{n} - 1 \le \frac{p-1}{n}$$

possibilities for choosing  $t_{\mathcal{Y}}$  such that the final hash-value creates a collision.

This happens with probability at most  $\frac{1}{n}$ .

It is also possible to show that  $\mathcal{H}$  is an (almost) pairwise independent class of hash-functions.

$$\frac{\left\lfloor \frac{p}{n} \right\rfloor^2}{p(p-1)} \le \Pr_{t_x \neq t_y \in \mathbb{Z}_p^2} \left[ \begin{array}{c} t_x \bmod n = h_1 \\ t_y \bmod n = h_2 \end{array} \right] \le \frac{\left\lceil \frac{p}{n} \right\rceil^2}{p(p-1)}$$

Note that the middle is the probability that  $h(x) = h_1$  and  $h(y) = h_2$ . The total number of choices for  $(t_x, t_y)$  is p(p-1). The number of choices for  $t_x$  ( $t_y$ ) such that  $t_x \mod n = h_1$  $(t_y \mod n = h_2)$  lies between  $\lfloor \frac{p}{n} \rfloor$  and  $\lceil \frac{p}{n} \rceil$ .

7.7 Hashing

9. lan. 2023 182/344

# **Universal Hashing**

For the coefficients  $\bar{a} \in \{0, \dots, q-1\}^{d+1}$  let  $f_{\bar{a}}$  denote the polynomial

$$f_{\bar{a}}(x) = \left(\sum_{i=0}^{d} a_i x^i\right) \bmod q$$

The polynomial is defined by d+1 distinct points.

## **Universal Hashing**

#### **Definition 18**

Let  $d \in \mathbb{N}$ ;  $q \ge (d+1)n$  be a prime; and let  $\bar{a} \in \{0, \dots, q-1\}^{d+1}$ . Define for  $x \in \{0, \dots, q-1\}$ 

$$h_{\tilde{a}}(x) := \left(\sum_{i=0}^{d} a_i x^i \mod q\right) \mod n$$
.

Let  $\mathcal{H}_n^d := \{h_{\bar{a}} \mid \bar{a} \in \{0, \dots, q-1\}^{d+1}\}$ . The class  $\mathcal{H}_n^d$  is (e, d+1)-independent.

Note that in the previous case we had d = 1 and chose  $a_d \neq 0$ .

7.7 Hashing

9. lan. 2023

183/344

# **Universal Hashing**

Fix  $\ell \le d+1$ ; let  $x_1, \dots, x_\ell \in \{0, \dots, q-1\}$  be keys, and let  $t_1, \ldots, t_\ell$  denote the corresponding hash-function values.

Let 
$$A^{\ell} = \{h_{\bar{a}} \in \mathcal{H} \mid h_{\bar{a}}(x_i) = t_i \text{ for all } i \in \{1, \dots, \ell\}\}$$
  
Then

$$h_{\bar{a}} \in A^{\ell} \Leftrightarrow h_{\bar{a}} = f_{\bar{a}} \bmod n$$
 and

$$f_{\bar{a}}(x_i) \in \underbrace{\{t_i + \alpha \cdot n \mid \alpha \in \{0, \dots, \lceil \frac{q}{n} \rceil - 1\}\}}_{=:B_i}$$

In order to obtain the cardinality of  $A^{\ell}$  we choose our polynomial by fixing d+1 points.

We first fix the values for inputs  $x_1, \ldots, x_\ell$ . We have

$$|B_1|\cdot\ldots\cdot|B_\ell|$$

possibilities to do this (so that  $h_{\bar{a}}(x_i) = t_i$ ).

 $\bullet$   $A^{\ell}$  denotes the set of hashfunctions such that every  $x_i$ hits its pre-defined position

•  $B_i$  is the set of positions that  $f_{\bar{a}}$  can hit so that  $h_{\bar{a}}$  still hits

Now, we choose  $d-\ell+1$  other inputs and choose their value arbitrarily. We have  $q^{d-\ell+1}$  possibilities to do this.

Therefore we have

$$|B_1| \cdot \ldots \cdot |B_\ell| \cdot q^{d-\ell+1} \le \lceil \frac{q}{n} \rceil^\ell \cdot q^{d-\ell+1}$$

possibilities to choose  $\bar{a}$  such that  $h_{\bar{a}} \in A_{\ell}$ .

Harald Räcke

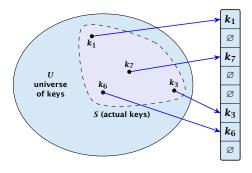

7.7 Hashing

186/344

## **Perfect Hashing**

Suppose that we **know** the set S of actual keys (no insert/no delete). Then we may want to design a **simple** hash-function that maps all these keys to different memory locations.

## **Universal Hashing**

Therefore the probability of choosing  $h_{\bar{a}}$  from  $A_{\ell}$  is only

$$\frac{\lceil \frac{q}{n} \rceil^{\ell} \cdot q^{d-\ell+1}}{q^{d+1}} \le \frac{\left(\frac{q+n}{n}\right)^{\ell}}{q^{\ell}} \le \left(\frac{q+n}{q}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \\
\le \left(1 + \frac{1}{\ell}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \le \frac{e}{n^{\ell}} .$$

This shows that the  $\mathcal{H}$  is (e, d+1)-universal.

The last step followed from  $q \ge (d+1)n$ , and  $\ell \le d+1$ .

Harald Räcke

7.7 Hashing

9. Jan. 2023

187/344

# **Perfect Hashing**

Let m = |S|. We could simply choose the hash-table size very large so that we don't get any collisions.

Using a universal hash-function the expected number of collisions is

$$E[\#Collisions] = \binom{m}{2} \cdot \frac{1}{n} .$$

If we choose  $n=m^2$  the expected number of collisions is strictly less than  $\frac{1}{2}$ .

Can we get an upper bound on the probability of having collisions?

The probability of having 1 or more collisions can be at most  $\frac{1}{2}$  as otherwise the expectation would be larger than  $\frac{1}{2}$ .

# **Perfect Hashing**

We can find such a hash-function by a few trials.

However, a hash-table size of  $n = m^2$  is very very high.

We construct a two-level scheme. We first use a hash-function that maps elements from  ${\cal S}$  to  ${\cal m}$  buckets.

Let  $m_j$  denote the number of items that are hashed to the j-th bucket. For each bucket we choose a second hash-function that maps the elements of the bucket into a table of size  $m_j^2$ . The second function can be chosen such that all elements are mapped to different locations.

7.7 Hashing

9. Jan. 2023

190/344

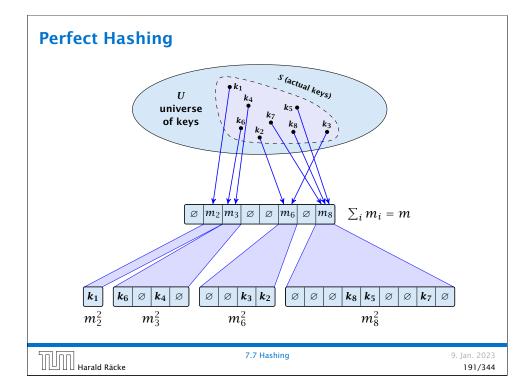

### **Perfect Hashing**

The total memory that is required by all hash-tables is  $\mathcal{O}(\sum_j m_j^2)$ . Note that  $m_j$  is a random variable.

$$E\left[\sum_{j} m_{j}^{2}\right] = E\left[2\sum_{j} {m_{j} \choose 2} + \sum_{j} m_{j}\right]$$
$$= 2E\left[\sum_{j} {m_{j} \choose 2}\right] + E\left[\sum_{j} m_{j}\right]$$

The first expectation is simply the expected number of collisions, for the first level. Since we use universal hashing we have

$$=2\binom{m}{2}\frac{1}{m}+m=2m-1.$$

# **Perfect Hashing**

We need only  $\mathcal{O}(m)$  time to construct a hash-function h with  $\sum_j m_j^2 = \mathcal{O}(4m)$ , because with probability at least 1/2 a random function from a universal family will have this property.

Then we construct a hash-table  $h_j$  for every bucket. This takes expected time  $\mathcal{O}(m_j)$  for every bucket. A random function  $h_j$  is collision-free with probability at least 1/2. We need  $\mathcal{O}(m_j)$  to test this.

We only need that the hash-functions are chosen from a universal family!!!

#### Goal:

Try to generate a hash-table with constant worst-case search time in a dynamic scenario.

- ► Two hash-tables  $T_1[0,...,n-1]$  and  $T_2[0,...,n-1]$ , with hash-functions  $h_1$ , and  $h_2$ .
- ▶ An object x is either stored at location  $T_1[h_1(x)]$  or  $T_2[h_2(x)]$ .
- A search clearly takes constant time if the above constraint is met.

9. lan. 2023

## **Cuckoo Hashing: Insert**

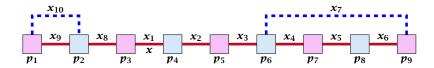

Harald Räcke

7.7 Hashing

9. Jan. 2023 199/344

**Cuckoo Hashing** 

A cycle-structure of size s is defined by

- ightharpoonup s-1 different cells (alternating btw. cells from  $T_1$  and  $T_2$ ).
- $\triangleright$  s distinct keys  $x = x_1, x_2, \dots, x_s$ , linking the cells.
- ▶ The leftmost cell is "linked forward" to some cell on the right.
- The rightmost cell is "linked backward" to a cell on the left.
- $\triangleright$  One link represents key x; this is where the counting starts.

# **Cuckoo Hashing**

A cycle-structure is active if for every key  $x_{\ell}$  (linking a cell  $p_i$  from  $T_1$  and a cell  $p_i$  from  $T_2$ ) we have

$$h_1(x_\ell) = p_i$$
 and  $h_2(x_\ell) = p_j$ 

#### Observation:

If during a phase the insert-procedure runs into a cycle there must exist an active cycle structure of size  $s \ge 3$ .

7.7 Hashing

9. lan. 2023 200/344 7.7 Hashing

9. Jan. 2023 201/344

What is the probability that all keys in a cycle-structure of size s correctly map into their  $T_1$ -cell?

This probability is at most  $\frac{\mu}{n^s}$  since  $h_1$  is a  $(\mu,s)$ -independent hash-function.

What is the probability that all keys in the cycle-structure of size s correctly map into their  $T_2$ -cell?

This probability is at most  $\frac{\mu}{n^s}$  since  $h_2$  is a  $(\mu, s)$ -independent hash-function.

These events are independent.

7.7 Hashing

9. Jan. 2023

202/344

### **Cuckoo Hashing**

The number of cycle-structures of size s is at most

$$s^3 \cdot n^{s-1} \cdot m^{s-1}$$

- ► There are at most  $s^2$  possibilities where to attach the forward and backward links.
- There are at most s possibilities to choose where to place key x.
- ▶ There are  $m^{s-1}$  possibilities to choose the keys apart from x.
- ▶ There are  $n^{s-1}$  possibilities to choose the cells.

# **Cuckoo Hashing**

The probability that a given cycle-structure of size s is active is at most  $\frac{\mu^2}{n^{2s}}$ .

What is the probability that there exists an active cycle structure of size *s*?

7.7 Hashing

9. Jan. 2023 203/344

## **Cuckoo Hashing**

The probability that there exists an active cycle-structure is therefore at most

$$\sum_{s=3}^{\infty} s^{3} \cdot n^{s-1} \cdot m^{s-1} \cdot \frac{\mu^{2}}{n^{2s}} = \frac{\mu^{2}}{nm} \sum_{s=3}^{\infty} s^{3} \left(\frac{m}{n}\right)^{s}$$

$$\leq \frac{\mu^{2}}{m^{2}} \sum_{s=3}^{\infty} s^{3} \left(\frac{1}{1+\epsilon}\right)^{s} \leq \mathcal{O}\left(\frac{1}{m^{2}}\right) .$$

Here we used the fact that  $(1 + \epsilon)m \le n$ .

Hence,

$$\Pr[\mathsf{cycle}] = \mathcal{O}\left(\frac{1}{m^2}\right)$$
.

Now, we analyze the probability that a phase is not successful without running into a closed cycle.

7.7 Hashing

9. lan. 2023

206/344

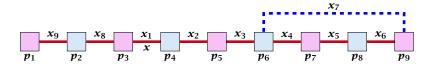

# **Cuckoo Hashing**

Consider the sequence of not necessarily distinct keys starting with x in the order that they are visited during the phase.

#### Lemma 19

If the sequence is of length p then there exists a sub-sequence of at least  $\frac{p+2}{3}$  keys starting with x of distinct keys.

# **Cuckoo Hashing**

Sequence of visited keys:

$$x = x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_3, x_2, x_1 = x, x_8, x_9, \dots$$

7.7 Hashing

9. Jan. 2023 207/344

# **Cuckoo Hashing**

Taking  $x_1 \rightarrow \cdots \rightarrow x_i$  twice, and  $x_1 \rightarrow x_{i+1} \rightarrow \cdots x_i$  once gives  $2i + (j - i + 1) = i + j + 1 \ge p + 2$  keys. Hence, one of the sequences contains at least (p+2)/3 keys.

#### Proof.

Let i be the number of keys (including x) that we see before the first repeated key. Let j denote the total number of distinct keys.

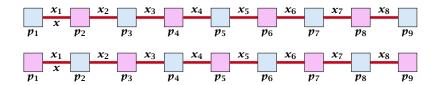

The sequence is of the form:

$$x = x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i \rightarrow x_r \rightarrow x_{r-1} \rightarrow \cdots \rightarrow x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$$

As  $r \le i - 1$  the length p of the sequence is

$$p = i + r + (j - i) \le i + j - 1$$
.

Either sub-sequence  $x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i$  or sub-sequence  $x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_i$  has at least  $\frac{p+2}{3}$  elements.

A path-structure of size s is defined by

- $\triangleright$  s+1 different cells (alternating btw. cells from  $T_1$  and  $T_2$ ).
- ightharpoonup s distinct keys  $x = x_1, x_2, \dots, x_s$ , linking the cells.
- ▶ The leftmost cell is either from  $T_1$  or  $T_2$ .

7.7 Hashing

9. lan. 2023

210/344

# **Cuckoo Hashing**

The probability that a given path-structure of size s is active is at most  $\frac{\mu^2}{n^{2s}}$ .

The probability that there exists an active path-structure of size s is at most

$$2 \cdot n^{s+1} \cdot m^{s-1} \cdot \frac{\mu^2}{n^{2s}}$$

$$\leq 2\mu^2 \left(\frac{m}{n}\right)^{s-1} \leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{s-1}$$

Plugging in s = (2t + 2)/3 gives

$$\leq 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t+2)/3-1} = 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t-1)/3} \ .$$

# **Cuckoo Hashing**

A path-structure is active if for every key  $x_{\ell}$  (linking a cell  $p_i$  from  $T_1$  and a cell  $p_i$  from  $T_2$ ) we have

$$h_1(x_\ell) = p_i$$
 and  $h_2(x_\ell) = p_j$ 

#### Observation:

If a phase takes at least t steps without running into a cycle there must exist an active path-structure of size (2t + 2)/3.

> Note that we count complete steps. A search that touches 2t or 2t + 1 keys takes t steps.

7.7 Hashing

9. lan. 2023 211/344

# **Cuckoo Hashing**

We choose maxsteps  $\geq 3\ell/2 + 1/2$ . Then the probability that a phase terminates unsuccessfully without running into a cycle is at most

Pr[unsuccessful | no cycle]

- $\leq \Pr[\exists \text{ active path-structure of size at least } \frac{2\text{maxsteps}+2}{2}]$
- $\leq \Pr[\exists \text{ active path-structure of size at least } \ell + 1]$
- $\leq \Pr[\exists \text{ active path-structure of size exactly } \ell + 1]$

$$\leq 2\mu^2 \Big(\frac{1}{1+\epsilon}\Big)^\ell \leq \frac{1}{m^2}$$

by choosing  $\ell \ge \log\left(\frac{1}{2\mu^2m^2}\right)/\log\left(\frac{1}{1+\epsilon}\right) = \log\left(2\mu^2m^2\right)/\log\left(1+\epsilon\right)$ 

This gives  $\max seps = \Theta(\log m)$ . Note that the existence of a path structure of size larger than s implies the existence of a path structure of size exactly s.

So far we estimated

$$\Pr[\mathsf{cycle}] \le \mathcal{O}\Big(\frac{1}{m^2}\Big)$$

and

$$\Pr[\mathsf{unsuccessful} \mid \mathsf{no} \; \mathsf{cycle}] \leq \mathcal{O}\Big(\frac{1}{m^2}\Big)$$

Observe that

$$Pr[successful] = Pr[no cycle] - Pr[unsuccessful | no cycle]$$
  
  $\geq c \cdot Pr[no cycle]$ 

for a suitable constant c > 0.

This is a very weak (and trivial) statement but still sufficient for our asymptotic analysis.

7.7 Hashing

9. Jan. 2023 214/344

# **Cuckoo Hashing**

The expected number of complete steps in the successful phase of an insert operation is:

E[number of steps | phase successful]

 $= \sum_{t \ge 1} \Pr[\text{search takes at least } t \text{ steps} \mid \text{phase successful}]$ 

We have

Pr[search at least t steps | successful]

- =  $Pr[search at least t steps \land successful] / Pr[successful]$
- $\leq \frac{1}{c} \Pr[\text{search at least } t \text{ steps } \land \text{ successful}] / \Pr[\text{no cycle}]$
- $\leq \frac{1}{c} \Pr[\text{search at least } t \text{ steps} \land \text{no cycle}] / \Pr[\text{no cycle}]$
- $=\frac{1}{c}\Pr[\text{search at least } t \text{ steps} \mid \text{no cycle}]$ .

# **Cuckoo Hashing**

Hence,

E[number of steps | phase successful]

$$\leq \frac{1}{c} \sum_{t \geq 1} \Pr[\text{search at least } t \text{ steps} \mid \text{no cycle}]$$

$$\leq \frac{1}{c} \sum_{t>1} 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t-1)/3} = \frac{1}{c} \sum_{t>0} 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2(t+1)-1)/3}$$

$$= \frac{2\mu^2}{c(1+\epsilon)^{1/3}} \sum_{t>0} \left(\frac{1}{(1+\epsilon)^{2/3}}\right)^t = \mathcal{O}(1) \ .$$

This means the expected cost for a successful phase is constant (even after accounting for the cost of the incomplete step that finishes the phase).

# **Cuckoo Hashing**

A phase that is not successful induces cost for doing a complete rehash (this dominates the cost for the steps in the phase).

The probability that a phase is not successful is  $q = \mathcal{O}(1/m^2)$  (probability  $\mathcal{O}(1/m^2)$  of running into a cycle and probability  $\mathcal{O}(1/m^2)$  of reaching maxsteps without running into a cycle).

A rehash try requires m insertions and takes expected constant time per insertion. It fails with probability  $p:=\mathcal{O}(1/m)$ .

The expected number of unsuccessful rehashes is  $\sum_{i\geq 1} p^i = \frac{1}{1-p} - 1 = \frac{p}{1-p} = \mathcal{O}(p)$ .

Therefore the expected cost for re-hashes is  $\mathcal{O}(m) \cdot \mathcal{O}(p) = \mathcal{O}(1)$ .

#### **Formal Proof**

Let  $Y_i$  denote the event that the i-th rehash occurs and does not lead to a valid configuration (i.e., one of the m+1 insertions fails):

$$\Pr[Y_i|Z_i] \le (m+1) \cdot \mathcal{O}(1/m^2) \le \mathcal{O}(1/m) =: \mathbf{p}.$$

Let  $Z_i$  denote the event that the *i*-th rehash occurs:

The 0-th (re)hash is the initial configuration when doing the insert. 
$$\Pr[Z_i] \leq \prod_{j=0}^{i-1} \Pr[Y_h \mid Z_j] \leq p^i$$

Let  $X_i^s$ ,  $s \in \{1, ..., m+1\}$  denote the cost for inserting the s-th element during the i-th rehash (assuming i-th rehash occurs):

$$\begin{split} \mathbf{E}[X_{t}^{\mathit{S}}] &= \mathbf{E}[\mathsf{steps} \mid \mathsf{phase} \; \mathsf{successful}] \cdot \Pr[\mathsf{phase} \; \mathsf{sucessful}] \\ &+ \mathsf{maxsteps} \cdot \Pr[\mathsf{not} \; \mathsf{sucessful}] = \mathcal{O}(1) \;\;. \end{split}$$

# **Cuckoo Hashing**

#### What kind of hash-functions do we need?

Since maxsteps is  $\Theta(\log m)$  the largest size of a path-structure or cycle-structure contains just  $\Theta(\log m)$  different keys.

Therefore, it is sufficient to have  $(\mu, \Theta(\log m))$ -independent hash-functions.

The expected cost for all rehashes is

$$E\left[\sum_{i}\sum_{s}Z_{i}X_{i}^{s}\right]$$

Note that  $Z_i$  is independent of  $X_j^s$ ,  $j \ge i$  (however, it is not independent of  $X_j^s$ , j < i). Hence,

$$E\left[\sum_{i}\sum_{s}Z_{i}X_{s}^{i}\right] = \sum_{i}\sum_{s}E[Z_{i}] \cdot E[X_{s}^{i}]$$

$$\leq \mathcal{O}(m) \cdot \sum_{i}p^{i}$$

$$\leq \mathcal{O}(m) \cdot \frac{p}{1-p}$$

$$= \mathcal{O}(1) .$$

Harald Räcke

7.7 Hashing

9. Jan. 2023 219/344

### **Cuckoo Hashing**

How do we make sure that  $n \ge (1 + \epsilon)m$ ?

- ▶ Let  $\alpha := 1/(1 + \epsilon)$ .
- ► Keep track of the number of elements in the table. When  $m \ge \alpha n$  we double n and do a complete re-hash (table-expand).
- Whenever m drops below  $\alpha n/4$  we divide n by 2 and do a rehash (table-shrink).
- Note that right after a change in table-size we have  $m=\alpha n/2$ . In order for a table-expand to occur at least  $\alpha n/2$  insertions are required. Similar, for a table-shrink at least  $\alpha n/4$  deletions must occur.
- ► Therefore we can amortize the rehash cost after a change in table-size against the cost for insertions and deletions.

#### Lemma 20

Cuckoo Hashing has an expected constant insert-time and a worst-case constant search-time.

Note that the above lemma only holds if the fill-factor (number of keys/total number of hash-table slots) is at most  $\frac{1}{2(1+\epsilon)}$ .

The  $1/(2(1+\epsilon))$  fill-factor comes from the fact that the total hash-table is of size 2n (because we have two tables of size n); moreover  $m \le n$ 

7.7 Hashing

# **8 Priority Queues**

A Priority Queue S is a dynamic set data structure that supports the following operations:

- $\triangleright$  S. build  $(x_1, \ldots, x_n)$ : Creates a data-structure that contains just the elements  $x_1, \ldots, x_n$ .
- $\triangleright$  S. insert(x): Adds element x to the data-structure.
- element S. minimum(): Returns an element  $x \in S$  with minimum key-value key[x].
- element S. delete-min(): Deletes the element with minimum key-value from S and returns it.
- **boolean** *S.* **is-empty**(): Returns true if the data-structure is empty and false otherwise.

Sometimes we also have

 $\triangleright$  S. merge(S'):  $S := S \cup S'$ :  $S' := \emptyset$ .

# **8 Priority Queues**

Harald Räcke

An addressable Priority Queue also supports:

- **handle** S. insert(x): Adds element x to the data-structure, and returns a handle to the object for future reference.
- $\triangleright$  S. delete(h): Deletes element specified through handle h.
- $\triangleright$  S. decrease-key(h, k): Decreases the key of the element specified by handle h to k. Assumes that the key is at least kbefore the operation.

## Dijkstra's Shortest Path Algorithm

```
Algorithm 39 Shortest-Path(G = (V, E, d), s \in V)
 1: Input: weighted graph G = (V, E, d); start vertex s;
 2: Output: key-field of every node contains distance from s;
 3: S.build(); // build empty priority queue
 4: for all v \in V \setminus \{s\} do
          v.\ker \leftarrow \infty;
          h_v \leftarrow S.insert(v);
 7: s. \text{key} \leftarrow 0; S. \text{insert}(s);
 8: while S.is-empty() = false do
          v \leftarrow S. delete-min();
          for all x \in V s.t. (v, x) \in E do
10:
                if x. key > v. key +d(v,x) then
11:
12:
                      S.decrease-key(h_x, v. key +d(v, x));
                      x. \text{key} \leftarrow v. \text{key} + d(v, x);
13:
```

decrease-key	$\log n$	$\log n$	$\log n$	1
merge	n	$n \log n$	$\log n$	1

# **Binary Heaps**

The standard implementation of binary heaps is via arrays. Let  $A[0,\ldots,n-1]$  be an array

- ▶ The parent of *i*-th element is at position  $\lfloor \frac{i-1}{2} \rfloor$ .
- ▶ The left child of i-th element is at position 2i + 1.
- ▶ The right child of i-th element is at position 2i + 2.

Finding the successor of x is much easier than in the description on the previous slide. Simply increase or decrease x.

The resulting binary heap is not addressable. The elements don't maintain their positions and therefore there are no stable handles.

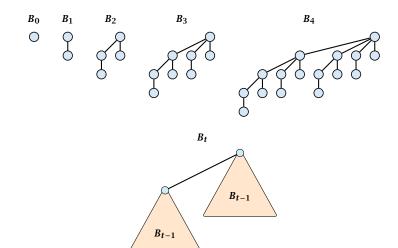

8.1 Binary Heaps

9. Jan. 2023

238/344

# **Binomial Trees**

#### **Binomial Trees**

#### **Properties of Binomial Trees**

- $ightharpoonup B_k$  has  $2^k$  nodes.
- $\triangleright$   $B_k$  has height k.
- ▶ The root of  $B_k$  has degree k.
- ▶  $B_k$  has  $\binom{k}{\ell}$  nodes on level  $\ell$ .
- ▶ Deleting the root of  $B_k$  gives trees  $B_0, B_1, \dots, B_{k-1}$ .

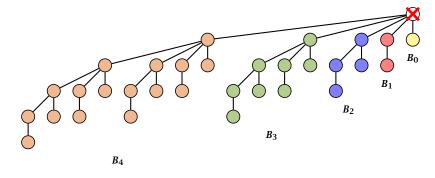

Harald Räcke

8.2 Binomial Heaps

9. Jan. 2023

241/344

#### **Binomial Trees**

Deleting the root of  $B_5$  leaves sub-trees  $B_4$ ,  $B_3$ ,  $B_2$ ,  $B_1$ , and  $B_0$ .

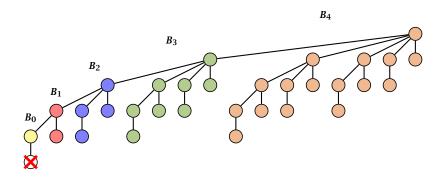

Harald Räcke

8.2 Binomial Heaps

9. Jan. 2023

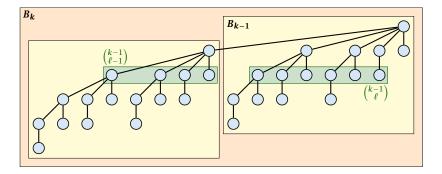

242/344

#### **Binomial Trees**

Deleting the leaf furthest from the root (in  $B_5$ ) leaves a path that connects the roots of sub-trees  $B_4$ ,  $B_3$ ,  $B_2$ ,  $B_1$ , and  $B_0$ .

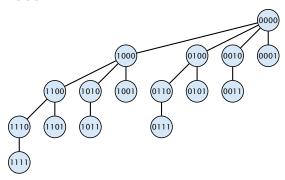

### **Binomial Trees**

The number of nodes on level  $\ell$  in tree  $B_k$  is therefore

$$\begin{pmatrix} k-1\\ \ell-1 \end{pmatrix} + \begin{pmatrix} k-1\\ \ell \end{pmatrix} = \begin{pmatrix} k\\ \ell \end{pmatrix}$$

#### **Binomial Trees**

The binomial tree  $B_k$  is a sub-graph of the hypercube  $H_k$ .

The parent of a node with label  $b_k, \ldots, b_1$  is obtained by setting the least significant 1-bit to 0.

The  $\ell$ -th level contains nodes that have  $\ell$  1's in their label.

Harald Räcke

245/344

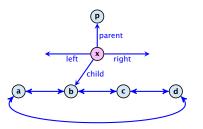

# 8.2 Binomial Heaps

- ► Given a pointer to a node *x* we can splice out the sub-tree rooted at *x* in constant time.
- ► We can add a child-tree *T* to a node *x* in constant time if we are given a pointer to *x* and a pointer to the root of *T*.

# 8.2 Binomial Heaps

#### How do we implement trees with non-constant degree?

- ▶ The children of a node are arranged in a circular linked list.
- A child-pointer points to an arbitrary node within the list.
- A parent-pointer points to the parent node.
- Pointers x. left and x. right point to the left and right sibling of x (if x does not have siblings then x. left = x. right = x).

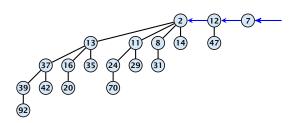

Harald Räcke

8.2 Binomial Heaps

9. Jan. 2023 246/344

# **Binomial Heap**

In a binomial heap the keys are arranged in a collection of binomial trees.

Every tree fulfills the heap-property

There is at most one tree for every dimension/order. For example the above heap contains trees  $B_0$ ,  $B_1$ , and  $B_4$ .

### **Binomial Heap: Merge**

Given the number n of keys to be stored in a binomial heap we can deduce the binomial trees that will be contained in the collection.

Let  $B_{k_1}$ ,  $B_{k_2}$ ,  $B_{k_3}$ ,  $k_i < k_{i+1}$  denote the binomial trees in the collection and recall that every tree may be contained at most once.

Then  $n = \sum_{i} 2^{k_i}$  must hold. But since the  $k_i$  are all distinct this means that the  $k_i$  define the non-zero bit-positions in the binary representation of n.

Harald Räcke

8.2 Binomial Heaps

249/344

# **Binomial Heap: Merge**

The merge-operation is instrumental for binomial heaps.

A merge is easy if we have two heaps with different binomial trees. We can simply merge the tree-lists.

Note that we do not just do a concatenation as we want to keep the trees in the list sorted according to size.

Otherwise, we cannot do this because the merged heap is not allowed to contain two trees of the same order.

Merging two trees of the same size: Add the tree with larger root-value as a child to the other tree.

For more trees the technique is analogous to binary addition.

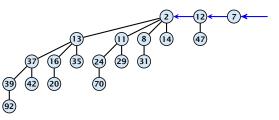

8.2 Binomial Heaps

#### 9. Ian. 2023 251/344

## **Binomial Heap**

#### Properties of a heap with n keys:

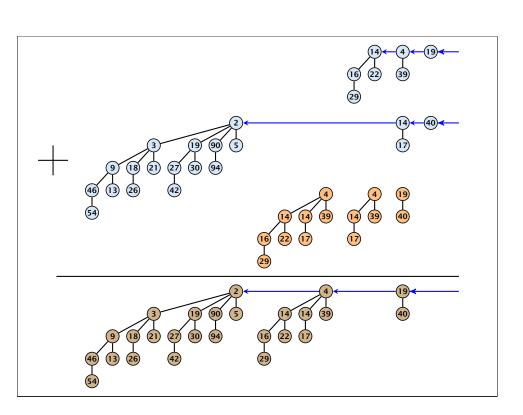

- Let  $n = b_d b_{d-1}, \dots, b_0$  denote binary representation of n.
- ▶ The heap contains tree  $B_i$  iff  $b_i = 1$ .
- ▶ Hence, at most  $|\log n| + 1$  trees.
- ▶ The minimum must be contained in one of the roots.
- ▶ The height of the largest tree is at most  $|\log n|$ .
- ► The trees are stored in a single-linked list; ordered by dimension/size.

Harald Räcke

# 8.3 Fibonacci Heaps

#### Consolidate:

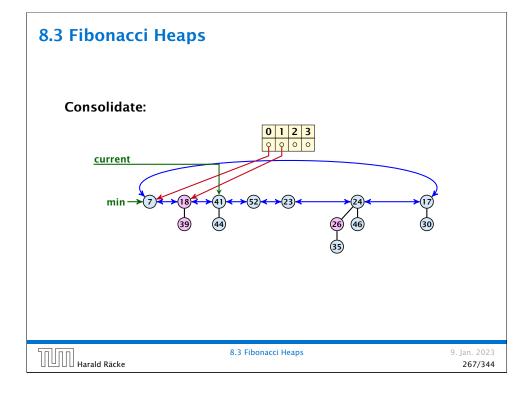

|||∐|||| <sub>Harald Räcke</sub>

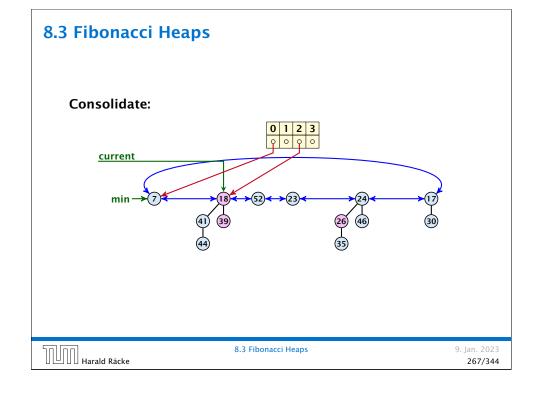

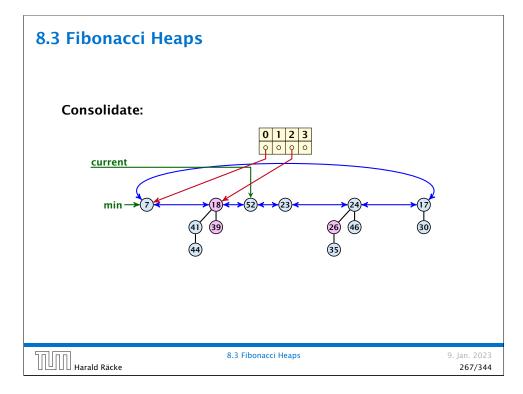

During the consolidation we traverse the root list. Whenever we discover two trees that have the same degree we merge these trees. In order to efficiently check whether two trees have the same degree, we use an array that contains  $\frac{1}{2}$  for every degree value d a pointer to a tree left of the current pointer whose root has degree d (if such a tree exist).

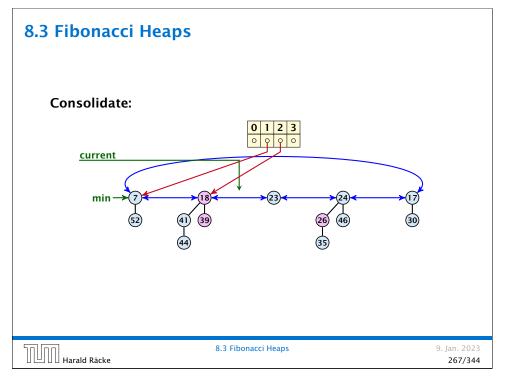

9. lan. 2023 266/344

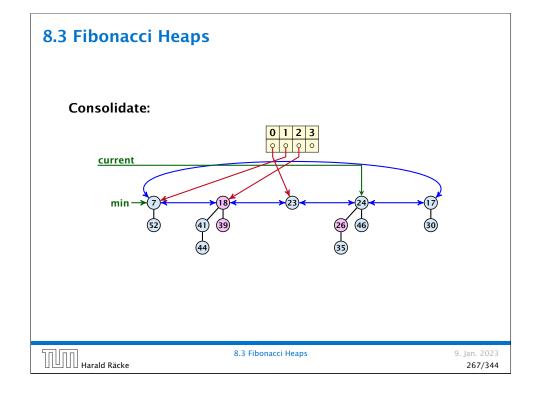

9. lan. 2023 267/344

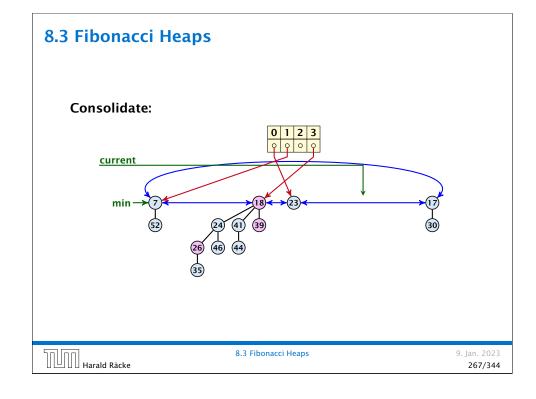

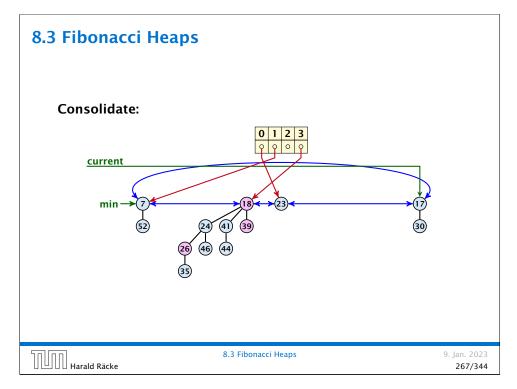

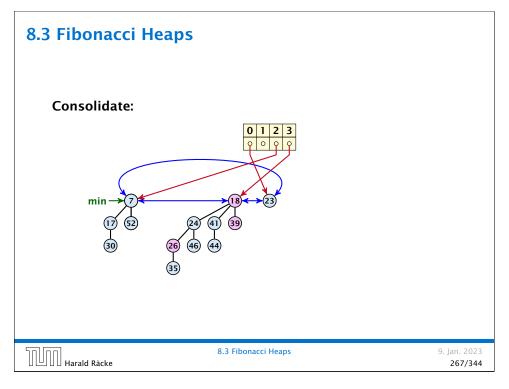

## 8.3 Fibonacci Heaps

t and t' denote the number of trees before and after the delete-min() operation, respectively.  $D_n$  is an upper bound on the degree (i.e., number of children) of a tree node.

#### Actual cost for delete-min()

- At most  $D_n + t$  elements in root-list before consolidate.
- Actual cost for a delete-min is at most  $\mathcal{O}(1) \cdot (D_n + t)$ . Hence, there exists  $c_1$  s.t. actual cost is at most  $c_1 \cdot (D_n + t)$ .

#### Amortized cost for delete-min()

- $t' \le D_n + 1$  as degrees are different after consolidating.
- ► Therefore  $\Delta \Phi \leq D_n + 1 t$ ;
- We can pay  $c \cdot (t D_n 1)$  from the potential decrease.
- ▶ The amortized cost is

$$c_1 \cdot (D_n + t) - c \cdot (t - D_n - 1)$$

$$\leq (c_1 + c)D_n + (c_1 - c)t + c \leq 2c(D_n + 1) \leq \mathcal{O}(D_n)$$
for  $c \geq c_1$ .

### Fibonacci Heaps: decrease-key(handle h, v)

#### Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element *x* reference by *h*.
- Cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Continue cutting the parent until you arrive at an unmarked node.

### Fibonacci Heaps: decrease-key(handle h, v)

#### Case 3: heap-property is violated, and parent is marked

- ightharpoonup Decrease key-value of element x reference by h.
- Cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Continue cutting the parent until you arrive at an unmarked node.

Harald Räcke

8.3 Fibonacci Heaps

9. Jan. 2023

Marking a node can be viewed as a in this first step towards becoming a root.

The first time x loses a child it is

marked; the second time it loses a child it is made into a root.

270/344

# Fibonacci Heaps: decrease-key(handle h, v)

#### Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element *x* reference by *h*.
- Cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Execute the following:

 $p \leftarrow parent[x];$  while (p is marked)

 $pp \leftarrow parent[p];$ 

cut of p; make it into a root; unmark it;

 $p \leftarrow pp$ ;

if p is unmarked and not a root mark it;

# Fibonacci Heaps: decrease-key(handle h, v)

#### Actual cost:

- Constant cost for decreasing the value.
- ightharpoonup Constant cost for each of  $\ell$  cuts.
- ▶ Hence, cost is at most  $c_2 \cdot (\ell + 1)$ , for some constant  $c_2$ .

#### Amortized cost:

- $t' = t + \ell$ , as every cut creates one new root.
- $m' \le m (\ell 1) + 1 = m \ell + 2$ , since all but the first cut unmarks a node; the last cut may mark a node.
- $\Delta \Phi \le \ell + 2(-\ell + 2) = 4 \ell$
- Amortized cost is at most

# 8.3 Fibonacci Heaps

#### Lemma 21

Let x be a node with degree k and let  $y_1, \dots, y_k$  denote the children of x in the order that they were linked to x. Then

$$degree(y_i) \ge \begin{cases} 0 & if i = 1\\ i - 2 & if i > 1 \end{cases}$$

The marking process is very important for the proof of this lemma. It ensures that a node can have lost at most one child since the last time it became a non-root node. When losing a first child the node gets marked: when losing the second child it is cut from the parent and made into a root.

8.3 Fibonacci Heaps

# 8.3 Fibonacci Heaps

#### Proof

- $\blacktriangleright$  When  $y_i$  was linked to x, at least  $y_1, \ldots, y_{i-1}$  were already linked to x.
- ▶ Hence, at this time degree(x)  $\geq i-1$ , and therefore also  $degree(y_i) \ge i - 1$  as the algorithm links nodes of equal degree only.
- $\triangleright$  Since, then  $y_i$  has lost at most one child.
- ▶ Therefore, degree( $\gamma_i$ ) ≥ i 2.

### 8.3 Fibonacci Heaps

- $\triangleright$  Let  $s_k$  be the minimum possible size of a sub-tree rooted at a node of degree k that can occur in a Fibonacci heap.
- $\triangleright$   $s_k$  monotonically increases with k
- $ightharpoonup s_0 = 1 \text{ and } s_1 = 2.$

Let x be a degree k node of size  $s_k$  and let  $y_1, \ldots, y_k$  be its children.

$$s_k = 2 + \sum_{i=2}^k \operatorname{size}(y_i)$$

$$\geq 2 + \sum_{i=2}^k s_{i-2}$$

$$= 2 + \sum_{i=0}^{k-2} s_i$$

8.3 Fibonacci Heaps

9. lan. 2023

276/344

k=0: 
$$1 = F_0 \ge \Phi^0 = 1$$
  
k=1:  $2 = F_1 \ge \Phi^1 \approx 1.61$   
k-2,k-1  $\rightarrow$  k:  $F_k = F_{k-1} + F_{k-2} \ge \Phi^{k-1} + \Phi^{k-2} = \Phi^{k-2}(\Phi^{+1}) = \Phi^k$ 

**k=2**: 
$$3 = F_2 = 2 + 1 = 2 + F_0$$

k=2: 
$$3 = F_2 = 2 + 1 = 2 + F_0$$
  
k-1  $\rightarrow$  k:  $F_k = F_{k-1} + F_{k-2} = 2 + \sum_{i=0}^{k-3} F_i + F_{k-2} = 2 + \sum_{i=0}^{k-2} F_i$ 

### 8.3 Fibonacci Heaps

 $\phi = \frac{1}{2}(1+\sqrt{5})$  denotes the *golden ratio*. Note that  $\phi^2 = 1+\phi$ .

#### **Definition 22**

Consider the following non-standard Fibonacci type sequence:

$$F_k = \begin{cases} 1 & \text{if } k = 0 \\ 2 & \text{if } k = 1 \\ F_{k-1} + F_{k-2} & \text{if } k \ge 2 \end{cases}$$

#### Facts:

- 1.  $F_k \geq \phi^k$ .
- **2.** For  $k \ge 2$ :  $F_k = 2 + \sum_{i=0}^{k-2} F_i$ .

The above facts can be easily proved by induction. From this it follows that  $s_k \ge F_k \ge \phi^k$ , which gives that the maximum degree in a Fibonacci heap is logarithmic.

### **List Implementation**

#### Lemma 23

The list implementation for the ADT union find fulfills the following amortized time bounds:

ightharpoonup find(x):  $\mathcal{O}(1)$ .

ightharpoonup makeset(x):  $\mathcal{O}(\log n)$ .

ightharpoonup union(x, y):  $\mathcal{O}(1)$ .

9 Union Find

9. lan. 2023

286/344

- For an operation whose actual cost exceeds the amortized cost we charge the excess to the elements involved.
- In total we will charge at most  $\mathcal{O}(\log n)$  to an element (regardless of the request sequence).
- For each element a makeset operation occurs as the first operation involving this element.
- ▶ We inflate the amortized cost of the makeset-operation to  $\Theta(\log n)$ , i.e., at this point we fill the bank account of the element to  $\Theta(\log n)$ .
- Later operations charge the account but the balance never drops below zero.

### The Accounting Method for Amortized Time Bounds

- ▶ There is a bank account for every element in the data structure.
- Initially the balance on all accounts is zero.
- Whenever for an operation the amortized time bound exceeds the actual cost, the difference is credited to some bank accounts of elements involved.
- Whenever for an operation the actual cost exceeds the amortized time bound, the difference is charged to bank accounts of some of the elements involved.
- If we can find a charging scheme that guarantees that balances always stay positive the amortized time bounds are proven.

9 Union Find

9. lan. 2023

287/344

#### **List Implementation List Implementation**

**makeset**(x): The actual cost is  $\mathcal{O}(1)$ . Due to the cost inflation the amortized cost is  $O(\log n)$ .

find(x): For this operation we define the amortized cost and the actual cost to be the same. Hence, this operation does not change any accounts. Cost: O(1).

#### union(x, y):

- ▶ If  $S_X = S_Y$  the cost is constant; no bank accounts change.
- ▶ Otw. the actual cost is  $\mathcal{O}(\min\{|S_x|, |S_y|\})$ .
- $\blacktriangleright$  Assume wlog, that  $S_x$  is the smaller set; let c denote the hidden constant, i.e., the actual cost is at most  $c \cdot |S_x|$ .
- $\triangleright$  Charge c to every element in set  $S_x$ .

### **List Implementation**

#### Lemma 24

An element is charged at most  $\lfloor \log_2 n \rfloor$  times, where n is the total number of elements in the set system.

#### Proof.

Whenever an element x is charged the number of elements in x's set doubles. This can happen at most  $\lfloor \log n \rfloor$  times.

Harald Räcke

9 Union Find

9. Jan. 2023

290/344

### Implementation via Trees

#### makeset(x)

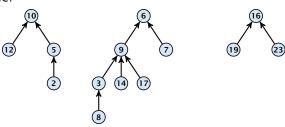

- Create a singleton tree. Return pointer to the root.
- ▶ Time:  $\mathcal{O}(1)$ .

#### find(x)

- Start at element x in the tree. Go upwards until you reach the root.
- ▶ Time:  $\mathcal{O}(\text{level}(x))$ , where level(x) is the distance of element x to the root in its tree. Not constant.

### **Implementation via Trees**

- Maintain nodes of a set in a tree.
- ▶ The root of the tree is the label of the set.
- Only pointer to parent exists; we cannot list all elements of a given set.
- Example:

Set system {2, 5, 10, 12}, {3, 6, 7, 8, 9, 14, 17}, {16, 19, 23}.

Harald Räcke

9 Union Find

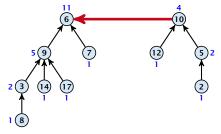

9. Jan. 2023 **291/344** 

### **Implementation via Trees**

To support union we store the size of a tree in its root.

#### union(x, y)

- ▶ Perform  $a \leftarrow \text{find}(x)$ ;  $b \leftarrow \text{find}(y)$ . Then: link(a, b).
- $\blacktriangleright$  link(a, b) attaches the smaller tree as the child of the larger.
- In addition it updates the size-field of the new root.

▶ Time: constant for link(a, b) plus two find-operations.

9 Union Find

9. Jan. 2023 **292/344**  9. Jan. 2023 293/344

### **Implementation via Trees**

#### Lemma 25

The running time (non-amortized!!!) for find(x) is  $O(\log n)$ .

#### Proof.

- ▶ When we attach a tree with root *c* to become a child of a tree with root p, then  $size(p) \ge 2 size(c)$ , where size denotes the value of the size-field right after the operation.
- $\blacktriangleright$  After that the value of size(c) stays fixed, while the value of size(p) may still increase.
- ▶ Hence, at any point in time a tree fulfills  $size(p) \ge 2 size(c)$ , for any pair of nodes (p,c), where p is a parent of c.

||||||||| Harald Räcke

9 Union Find

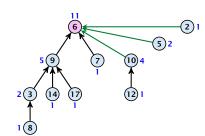

9. lan. 2023

294/344

### **Path Compression**

#### find(x):

- ► Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

One could change the algorithm to update the size-fields. This could be done without asymptotically affecting the running time.

However, the only size-field that is actually required is the field at the root, which is always correct.

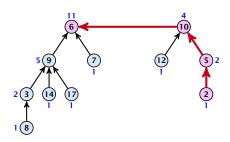

We will only use the other size-! fields for the proof of Theorem 28.

Note that the size-fields now only give an upper bound on the size of a sub-tree.

### **Path Compression**

#### find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

Note that the size-fields now only give an upper bound on the size of a sub-tree.

Harald Räcke

9 Union Find

9. lan. 2023

295/344

### **Path Compression**

Asymptotically the cost for a find-operation does not increase due to the path compression heuristic.

However, for a worst-case analysis there is no improvement on the running time. It can still happen that a find-operation takes time  $\mathcal{O}(\log n)$ .

### **Amortized Analysis**

#### **Definitions:**

▶ size(v) = the number of nodes that were in the sub-tree rooted at <math>v when v became the child of another node (or the number of nodes if v is the root).

Note that this is the same as the size of  $\nu$ 's subtree in the case that there are no find-operations.

- $ightharpoonup rank(v) = \lfloor \log(\text{size}(v)) \rfloor.$
- ightharpoonup  $\Rightarrow$  size $(v) \ge 2^{\operatorname{rank}(v)}$ .

#### Lemma 26

The rank of a parent must be strictly larger than the rank of a child.

9 Union Find

9. Jan. 2023

297/344

### **Amortized Analysis**

We define

and

$$\log^*(n) := \min\{i \mid \text{tow}(i) \ge n\} .$$

#### **Theorem 28**

Union find with path compression fulfills the following amortized running times:

- ightharpoonup makeset(x) :  $\mathcal{O}(\log^*(n))$
- $ightharpoonup find(x) : \mathcal{O}(\log^*(n))$
- ▶ union(x, y) :  $\mathcal{O}(\log^*(n))$

## Harald Räcke

### **Amortized Analysis**

#### Lemma 27

There are at most  $n/2^s$  nodes of rank s.

#### Proof.

- Let's say a node v sees node x if v is in x's sub-tree at the time that x becomes a child.
- A node v sees at most one node of rank s during the running time of the algorithm.
- ► This holds because the rank-sequence of the roots of the different trees that contain v during the running time of the algorithm is a strictly increasing sequence.
- ► Hence, every node *sees* at most one rank s node, but every rank s node is seen by at least  $2^s$  different nodes.

9 Union Find

9. Jan. 2023

298/344

### **Amortized Analysis**

In the following we assume  $n \ge 2$ .

#### rank-group:

- ▶ A node with rank rank(v) is in rank group  $\log^*(\operatorname{rank}(v))$ .
- ► The rank-group g = 0 contains only nodes with rank 0 or rank 1.
- A rank group  $g \ge 1$  contains ranks tow(g-1)+1,...,tow(g).
- ► The maximum non-empty rank group is  $\log^*(\lfloor \log n \rfloor) \le \log^*(n) 1$  (which holds for  $n \ge 2$ ).
- $\blacktriangleright$  Hence, the total number of rank-groups is at most  $\log^* n$ .

### **Amortized Analysis**

#### **Accounting Scheme:**

- create an account for every find-operation
- ightharpoonup create an account for every node v

The cost for a find-operation is equal to the length of the path traversed. We charge the cost for going from v to parent[v] as follows:

- ► If parent[v] is the root we charge the cost to the find-account.
- ▶ If the group-number of rank(v) is the same as that of rank(parent[v]) (before starting path compression) we charge the cost to the node-account of v.
- ▶ Otherwise we charge the cost to the find-account.

9 Union Find

9. Jan. 2023

301/344

### **Amortized Analysis**

#### What is the total charge made to nodes?

► The total charge is at most

$$\sum_{g} n(g) \cdot \text{tow}(g) ,$$

where n(g) is the number of nodes in group g.

### **Amortized Analysis**

#### **Observations:**

- ▶ A find-account is charged at most  $\log^*(n)$  times (once for the root and at most  $\log^*(n) 1$  times when increasing the rank-group).
- After a node v is charged its parent-edge is re-assigned. The rank of the parent strictly increases.
- After some charges to v the parent will be in a larger rank-group.  $\Rightarrow v$  will never be charged again.
- ► The total charge made to a node in rank-group g is at most  $tow(g) tow(g-1) 1 \le tow(g)$ .

9 Union Find

9. Jan. 2023

302/344

### **Amortized Analysis**

For  $g \ge 1$  we have

$$n(g) \le \sum_{s=\text{tow}(g-1)+1}^{\text{tow}(g)} \frac{n}{2^s} \le \sum_{s=\text{tow}(g-1)+1}^{\infty} \frac{n}{2^s}$$

$$= \frac{n}{2^{\text{tow}(g-1)+1}} \sum_{s=0}^{\infty} \frac{1}{2^s} = \frac{n}{2^{\text{tow}(g-1)+1}} \cdot 2$$

$$= \frac{n}{2^{\text{tow}(g-1)}} = \frac{n}{\text{tow}(g)}.$$

Hence,

$$\sum_{g} n(g) \operatorname{tow}(g) \le n(0) \operatorname{tow}(0) + \sum_{g \ge 1} n(g) \operatorname{tow}(g) \le n \log^*(n)$$

9. Jan. 2023

### **Amortized Analysis**

Without loss of generality we can assume that all makeset-operations occur at the start.

This means if we inflate the cost of makeset to  $\log^* n$  and add this to the node account of v then the balances of all node accounts will sum up to a positive value (this is sufficient to obtain an amortized bound).

9 Union Find

9. Jan. 2023

9. Ian. 2023

307/344

305/344

### **Amortized Analysis**

$$A(x,y) = \begin{cases} y+1 & \text{if } x = 0\\ A(x-1,1) & \text{if } y = 0\\ A(x-1,A(x,y-1)) & \text{otw.} \end{cases}$$

$$\alpha(m, n) = \min\{i \ge 1 : A(i, \lfloor m/n \rfloor) \ge \log n\}$$

- A(0, y) = y + 1
- A(1, y) = y + 2
- A(2, y) = 2y + 3
- $A(3, y) = 2^{y+3} 3$
- ►  $A(4, y) = \underbrace{2^{2^2}}_{y+3 \text{ times}} -3$

#### 9 Union Find Harald Räcke

### **Amortized Analysis**

The analysis is not tight. In fact it has been shown that the amortized time for the union-find data structure with path compression is  $\mathcal{O}(\alpha(m,n))$ , where  $\alpha(m,n)$  is the inverse Ackermann function which grows a lot lot slower than  $\log^* n$ . (Here, we consider the average running time of m operations on at most n elements).

There is also a lower bound of  $\Omega(\alpha(m, n))$ .

## **Implementation 2: Summary Array**

9. Ian. 2023

- $ightharpoonup \sqrt{u}$  cluster-arrays of  $\sqrt{u}$  bits.
- One summary-array of  $\sqrt{u}$  bits. The *i*-th bit in the summary array stores the bit-wise or of the bits in the i-th cluster.

### **Implementation 2: Summary Array**

The bit for a key x is contained in cluster number  $\left| \frac{x}{\sqrt{y}} \right|$ .

Within the cluster-array the bit is at position  $x \mod \sqrt{u}$ .

For simplicity we assume that  $u = 2^{2k}$  for some  $k \ge 1$ . Then we can compute the cluster-number for an entry x as high(x) (the upper half of the dual representation of x) and the position of xwithin its cluster as low(x) (the lower half of the dual representation).

10 van Emde Boas Trees

9. lan. 2023

316/344

### **Implementation 2: Summary Array**

#### **Algorithm 10** delete(x)

- 1: cluster[high(x)]. delete(low(x));
- 2: **if** cluster[high(x)].min() = null **then**
- summary . delete(high(x));
- ▶ The running time is dominated by the cost of a minimum computation on an array of size  $\sqrt{u}$ . Hence,  $\mathcal{O}(\sqrt{u})$ .

### **Implementation 2: Summary Array**

```
Algorithm 8 member(x)
1: return cluster[high(x)].member(low(x));
```

```
Algorithm 9 insert(x)
1: cluster[high(x)].insert(low(x));
2: summary.insert(high(x));
```

▶ The running times are constant, because the corresponding array-functions have constant running times.

10 van Emde Boas Trees

The operator o stands

for the concatenation of two bitstrings.

This means if

 $x = 0111_2$  and

 $\nu = 0001_2$  then

 $x \circ y = 01110001_2$ .

### **Implementation 2: Summary Array**

### Algorithm 11 max()

- 1: *maxcluster* ← summary.max();
- 2: **if** *maxcluster* = null **return** null;
- 3: *offs* ← cluster[*maxcluster*].max()
- 4: **return** *maxcluster* ∘ *offs*;

### Algorithm 12 min()

- 1: *mincluster* ← summary.min();
- 2: **if** *mincluster* = null **return** null;
- 3:  $offs \leftarrow cluster[mincluster].min();$
- 4: **return** *mincluster* ∘ *offs*;

▶ Running time is roughly  $2\sqrt{u} = \mathcal{O}(\sqrt{u})$  in the worst case.

### **Implementation 2: Summary Array**

```
Algorithm 13 succ(x)
1: m \leftarrow \text{cluster}[\text{high}(x)]. \text{succ}(\text{low}(x))
2: if m \neq \text{null} then return \text{high}(x) \circ m;
3: succeluster \leftarrow summary.succ(high(x));
4: if succcluster ≠ null then
         offs ← cluster[succcluster].min();
         return succeluster ∘ offs;
7: return null;
```

▶ Running time is roughly  $3\sqrt{u} = \mathcal{O}(\sqrt{u})$  in the worst case.

Harald Räcke

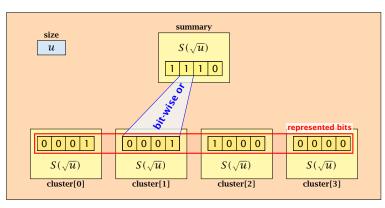

10 van Emde Boas Trees

9. lan. 2023 320/344

### **Implementation 3: Recursion**

Instead of using sub-arrays, we build a recursive data-structure.

S(u) is a dynamic set data-structure representing u bits:

### **Implementation 2: Summary Array**

### Algorithm 14 pred(x)1: $m \leftarrow \text{cluster}[\text{high}(x)]. \text{pred}(\text{low}(x))$ 2: if $m \neq \text{null}$ then return $high(x) \circ m$ ; 3: $predcluster \leftarrow summary.pred(high(x))$ ; 4: **if** *predcluster* ≠ null **then** $offs \leftarrow cluster[predcluster].max();$ **return** *predcluster* • *offs*; 7: return null;

▶ Running time is roughly  $3\sqrt{u} = \mathcal{O}(\sqrt{u})$  in the worst case.

Harald Räcke

10 van Emde Boas Trees

9. lan. 2023 321/344

### **Implementation 3: Recursion**

We assume that  $u = 2^{2^k}$  for some k.

The data-structure S(2) is defined as an array of 2-bits (end of the recursion).

### **Implementation 3: Recursion**

The code from Implementation 2 can be used unchanged. We only need to redo the analysis of the running time.

Note that in the code we do not need to specifically address the non-recursive case. This is achieved by the fact that an S(4) will contain S(2)'s as sub-datastructures, which are arrays. Hence, a call like cluster[1]. min() from within the data-structure S(4) is not a recursive call as it will call the function array.min().

This means that the non-recursive case is been dealt with while initializing the data-structure.

### **Implementation 3: Recursion**

#### $T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$ :

Set 
$$\ell := \log u$$
 and  $X(\ell) := T_{\text{mem}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{mem}}(2^{\ell}) = T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$$
  
=  $T_{\text{mem}}(2^{\frac{\ell}{2}}) + 1 = X(\frac{\ell}{2}) + 1$ .

Using Master theorem gives  $X(\ell) = \mathcal{O}(\log \ell)$ , and hence  $T_{\text{mem}}(u) = \mathcal{O}(\log \log u)$ .

### **Implementation 3: Recursion**

$$T_{\rm ins}(u) = 2T_{\rm ins}(\sqrt{u}) + 1.$$

Set 
$$\ell := \log u$$
 and  $X(\ell) := T_{\text{ins}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{ins}}(2^{\ell}) = T_{\text{ins}}(u) = 2T_{\text{ins}}(\sqrt{u}) + 1$$
$$= 2T_{\text{ins}}(2^{\frac{\ell}{2}}) + 1 = 2X(\frac{\ell}{2}) + 1 .$$

Using Master theorem gives  $X(\ell) = \mathcal{O}(\ell)$ , and hence  $T_{\text{ins}}(u) = \mathcal{O}(\log u)$ .

The same holds for  $T_{\text{max}}(u)$  and  $T_{\text{min}}(u)$ .

### **Implementation 3: Recursion**

$$T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1 \le 2T_{\text{del}}(\sqrt{u}) + \frac{c}{\log(u)}.$$

Set  $\ell := \log u$  and  $X(\ell) := T_{\text{del}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{del}}(2^{\ell}) = T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + c \log u$$
$$= 2T_{\text{del}}(2^{\frac{\ell}{2}}) + c\ell = 2X(\frac{\ell}{2}) + c\ell .$$

Using Master theorem gives  $X(\ell) = \Theta(\ell \log \ell)$ , and hence  $T_{\text{del}}(u) = \mathcal{O}(\log u \log \log u)$ .

The same holds for  $T_{\text{pred}}(u)$  and  $T_{\text{succ}}(u)$ .

#### **Implementation 4: van Emde Boas Trees**

#### Advantages of having max/min pointers:

- ▶ Recursive calls for min and max are constant time.
- ▶ min = null means that the data-structure is empty.
- $\mathbf{min} = \max \neq \text{null means that the data-structure contains}$ exactly one element.
- We can insert into an empty datastructure in constant time by only setting min = max = x.
- We can delete from a data-structure that just contains one element in constant time by setting min = max = null.

### **Implementation 4: van Emde Boas Trees**

- ► The bit referenced by min is not set within sub-datastructures.
- The bit referenced by max is set within sub-datastructures (if  $\max \neq \min$ ).

9. Ian. 2023 337/344

### **Implementation 4: van Emde Boas Trees**

```
Algorithm 65 insert(x)
1: if min = null then
        \min = x; \max = x;
3: else
       if x < \min then exchange x and \min;
       if cluster[high(x)]. min = null; then
5:
            summary.insert(high(x));
6:
7:
            cluster[high(x)].insert(low(x));
8:
        else
            cluster[high(x)].insert(low(x));
        if x > \max then \max = x;
10:
```

# $ightharpoonup T_{ins}(u) = T_{ins}(\sqrt{u}) + 1 \Longrightarrow T_{ins}(u) = \mathcal{O}(\log \log u).$

### **Implementation 4: van Emde Boas Trees**

Note that the recusive call in Line 7 takes constant time as the if-condition in Line 5 ensures that we are inserting in an empty sub-tree.

The only non-constant recursive calls are the call in Line 6 and in Line 9. These are mutually exclusive, i.e., only one of these calls will actually occur.

From this we get that  $T_{ins}(u) = T_{ins}(\sqrt{u}) + 1$ .

### **Implementation 4: van Emde Boas Trees**

Assumes that x is contained in the structure.

```
Algorithm 65 delete(x)
 1: if min = max then
        min = null; max = null;
 3: else
 4:
         if x = \min then
                                            find new minimum
 5:
              firstcluster \leftarrow summary.min();
              offs ← cluster[firstcluster].min();
 6:
              x \leftarrow firstcluster \circ offs;
 7:
              \min \leftarrow x;
 8:
        cluster[high(x)].delete(low(x));
 9:
                                                       delete
10:
        if cluster[high(x)]. min() = null then
              summary . delete(high(x));
11:
                         continued...
```

]]]]]]]]] Harald Räcke

10 van Emde Boas Trees

9. Jan. 2023 340/344

### **Implementation 4: van Emde Boas Trees**

Note that only one of the possible recusive calls in Line 9 and Line 11 in the deletion-algorithm may take non-constant time.

To see this observe that the call in Line 11 only occurs if the cluster where x was deleted is now empty. But this means that the call in Line 9 deleted the last element in cluster [high(x)]. Such a call only takes constant time.

Hence, we get a recurrence of the form

$$T_{\rm del}(u) = T_{\rm del}(\sqrt{u}) + c$$
.

This gives  $T_{\text{del}}(u) = \mathcal{O}(\log \log u)$ .

Harald Räcke

### **Implementation 4: van Emde Boas Trees**

```
Algorithm 65 delete(x)
                          ...continued
                                                  fix maximum
10:
        if x = \max then
11:
             summax \leftarrow summary.max();
             if summax = null then max \leftarrow min;
12:
13:
             else
                  offs \leftarrow cluster[summax].max();
14:
                  max \leftarrow summax \circ offs
15:
```

Harald Räcke

#### 10 van Emde Boas Trees

#### Space requirements:

► The space requirement fulfills the recurrence

$$S(u) = (\sqrt{u} + 1)S(\sqrt{u}) + \mathcal{O}(\sqrt{u}) .$$

- Note that we cannot solve this recurrence by the Master theorem as the branching factor is not constant.
- One can show by induction that the space requirement is  $S(u) = \mathcal{O}(u)$ . Exercise.

9. Ian. 2023

Let the "real" recurrence relation be

$$S(k^2) = (k+1)S(k) + c_1 \cdot k$$
;  $S(4) = c_2$ 

▶ Replacing S(k) by  $R(k) := S(k)/c_2$  gives the recurrence

$$R(k^2) = (k+1)R(k) + ck; R(4) = 1$$

where  $c = c_1/c_2 < 1$ .

- Now, we show  $R(k) \le k 2$  for squares  $k \ge 4$ .
  - ▶ Obviously, this holds for k = 4.
  - For  $k = \ell^2 > 4$  with  $\ell$  integral we have

$$R(k) = (1 + \ell)R(\ell) + c\ell$$
  

$$\leq (1 + \ell)(\ell - 2) + \ell \leq k - 2$$

▶ This shows that R(k) and, hence, S(k) grows linearly.
